## Alignment-class Alignments between sequences

## Description

The Alignment class will represent alignments between multiple sequences. Its design is not yet finalized.

## Annotated-class Annotated class

## Description

The virtual class Annotated is used to standardize the storage of metadata with a subclass.

## Details

The Annotated class supports the storage of global metadata in a subclass. This is done through the metadata slot that stores a list object.

## Accessors

In the following code snippets, x is an Annot ated object.
metadata(x), metadata(x) <- value: Get or set the list holding arbitrary $R$ objects as annotations. May be, and often is, empty.

## Author(s)

P. Aboyoun

## See Also

Sequence for example implementations

## Description

An extension of Sequence that holds only atomic vectors in either a natural or run-length encoded form.

## Details

The lists of atomic vectors are LogicalList, IntegerList, NumericList, ComplexList, CharacterList, and RawList. There is also an RleList class for run-length encoded versions of these atomic vector types.
Each of the above mentioned classes is virtual with Compressed* and Simple* non-virtual representations.

## Constructors

LogicalList(..., compress = TRUE):Concatenates the logical vectors in ... into a new LogicalList. If compress, the internal storage of the data is compressed.

IntegerList(..., compress = TRUE):Concatenates the integer vectors in ... into a new IntegerList. If compress, the internal storage of the data is compressed.

NumericList(..., compress = TRUE):Concatenates the numeric vectors in ... into a new NumericList. If compress, the internal storage of the data is compressed.
ComplexList(..., compress = TRUE): Concatenates the complex vectors in ... into a new ComplexList. If compress, the internal storage of the data is compressed.

CharacterList(..., compress = TRUE): Concatenates the character vectors in . . . into a new CharacterList. If compress, the internal storage of the data is compressed

RawList(..., compress = TRUE): Concatenates the raw vectors in ... into a new RawList. If compress, the internal storage of the data is compressed.

RleList(..., compress = FALSE): Concatenates the run-length encoded atomic vectors in . . . into a new RleList. If compress, the internal storage of the data is compressed.

## Coercion

as.vector (x), as (from, "vector"): Creates a vector based on the values contained in x.
as.logical(x), as(from, "logical"): Creates a logical vector based on the values contained in $x$.
as.integer(x), as(from, "integer"): Creates an integer vector based on the values contained in x .
as.numeric(x), as(from, "numeric"): Creates a numeric vector based on the values contained in $x$.
as.complex(x), as (from, "complex"): Creates a complex vector based on the values contained in x .
as.character(x), as (from, "character"): Creates a character vector based on the values contained in $x$.
as.raw(x), as (from, "raw"): Creates a raw vector based on the values contained in x .
as.factor(x), as (from, "factor"): Creates a factor object based on the values contained in x
as.data.frame(x, row.names = NULL, optional = FALSE), as (from, "data.frame"):
Creates a data.frame object based on the values contained in $x$. Essentially the same as calling data.frame (space=rep(names(x), elementLengths(x)), as.vector(x)).
as(from, "CompressedSplitDataFrameList"), as(from, "SimpleSplitDataFrameList"): Creates a CompressedSplitDataFrameList/SimpleSplitDataFrameList instance from an AtomicList instance.
as(from, "IRangesList"), as(from, "CompressedIRangesList"), as(from, "SimpleIRangesList"): Creates a CompressedIRangesList/SimpleIRangesList instance from a LogicalList or logical RleList instance. Note that the elements of this instance are guaranteed to be normal.
as(from, "NormalIRangesList"),as(from, "CompressedNormalIRangesList"), as (from, "SimpleNormalIRangesList"): Creates a CompressedNormalIRangesList/SimpleNormalIRangesList instance from a LogicalList or logical RleList instance.
as(from, "AtomicList"): If from is a vector, converts it to an AtomicList of the appropriate type.

## Group Generics

AtomicList objects have support for S4 group generic functionality to operate within elements across objects:

```
Arith "+", "-", "*", "^", "%%", "%/%", " / "
Compare "==", ">", "<", "!=", "<=", ">="
Logic "&","|"
Ops "Arith", "Compare", "Logic"
Math "abs","sign","sqrt","ceiling","floor", "trunc", "cummax", "cummin",
    "cumprod", "cumsum", "log", "log10", "log2", "log1p", "acos", "acosh",
    "asin", "asinh", "atan", "atanh", "exp", "expm1", "cos", "cosh", "sin",
    "sinh", "tan", "tanh", "gamma", "lgamma", "digamma", "trigamma"
Math2 "round","signif"
Summary "max", "min", "range", "prod", "sum", "any", "all"
Complex "Arg", "Conj", "Im", "Mod", "Re"
```

See S4groupGeneric for more details.

## Other Basic Methods

The AtomicList objects also support a large number of basic methods. Like the group generics above, these methods perform the corresponding operation on each element of the list separately. The methods are:

General \%in\%,is.na, match, sort, table, unique
Logical !, which

Numeric diff, pmax, pmax.int, pmin, pmin.int, mean, var, cov, cor, sd, median, quantile, mad, IQR
Running Window smoothEnds, runmed. runmean, runsum, runwtsum, runq
Character nchar, chartr, tolower, toupper, sub, gsub

## Author(s)

P. Aboyoun

## See Also

Sequence for the applicable methods.

## Examples

```
int1 <- c(1L,2L,3L,5L,2L,8L)
int2 <- c(15L,45L,20L,1L,15L,100L,80L,5L)
collection <- IntegerList(int1, int2)
## names
names(collection) <- c("one", "two")
names(collection)
names(collection) <- NULL # clear names
names(collection)
names(collection) <- "one"
names(collection) # c("one", NA)
## extraction
collection[[1]] # range1
collection[["1"]] # NULL, does not exist
collection[["one"]] # range1
collection[[NA_integer_]] # NULL
## subsetting
collection[numeric()] # empty
collection[NULL] # empty
collection[] # identity
collection[c(TRUE, FALSE)] # first element
collection[2] # second element
collection[c(2,1)] # reversed
collection[-1] # drop first
collection$one
## replacement
collection$one <- int2
collection[[2]] <- int1
## combining
col1 <- IntegerList(one = int1, int2)
col2 <- IntegerList(two = int2, one = int1)
col3 <- IntegerList(int2)
append(col1, col2)
append(col1, col2, 0)
c(col1, col2, col3)
## group generics
```

```
2 * col1
col1 + col1
col1 > 2
log(col1)
sum(col1)
## get the mean for each element
sapply(col1, mean)
```

DataFrame-class External Data Frame

## Description

The DataFrame extends the DataTable virtual class and supports the storage of any type of object (with length and [ methods) as columns.

## Details

On the whole, the DataFrame behaves very similarly to data.frame, in terms of construction, subsetting, splitting, combining, etc. The most notable exception is that the row names are optional. This means calling rownames $(x)$ will return NULL if there are no row names. Of course, it could return seq_len (nrow (x)), but returning NULL informs, for example, combination functions that no row names are desired (they are often a luxury when dealing with large data).
As DataFrame derives from Sequence, it is possible to set an annotation string. Also, another DataFrame can hold metadata on the columns.

## Accessors

In the following code snippets, x is a Dat aFrame.
$\operatorname{dim}(x)$ : Get the length two integer vector indicating in the first and second element the number of rows and columns, respectively.
dimnames(x), dimnames(x) <- value: Get and set the two element list containing the row names (character vector of length nrow (x) or NULL) and the column names (character vector of length $\mathrm{ncol}(\mathrm{x})$ ).

## Subsetting

In the following code snippets, x is a DataFrame.
$x[i, j, d r o p]:$ Behaves very similarly to the [.data.frame method, except i can be a logical Rle object and subsetting by matrix indices is not supported. Indices containing NA's are also not supported.
$x[i, j]<-$ value: Behaves very similarly to the [<-.data.frame method.
x[[i]]: Behaves very similarly to the [[.data.frame method, except arguments $j$ and exact are not supported. Column name matching is always exact. Subsetting by matrices is not supported.
$\mathrm{x}[$ [i]] <- value: Behaves very similarly to the [ [<-. data.frame method, except argument $j$ is not supported.

## Constructor

DataFrame(..., row.names = NULL): Constructs a DataFrame in similar fashion to data.frame. Each argument in ... is coerced to a DataFrame and combined column-wise. No special effort is expended to automatically determine the row names from the arguments. The row names should be given in row. names; otherwise, there are no row names. This is by design, as row names are normally undesirable when data is large.

## Splitting and Combining

In the following code snippets, $x$ is a DataFrame.
split(x, f, drop = FALSE): Splits x into a CompressedSplitDataFrameList, according to $f$, dropping elements corresponding to unrepresented levels if drop is TRUE.
rbind (...): Creates a new DataFrame by combining the rows of the DataFrame objects in . . . Very similar to rbind. data.frame, except in the handling of row names. If all elements have row names, they are concatenated and made unique. Otherwise, the result does not have row names. Currently, factors are not handled well (their levels are dropped). This is not a high priority until there is an XFactor class.
cbind (...): Creates a new DataFrame by combining the columns of the DataFrame objects in . ... Very similar to cbind. data.frame, except row names, if any, are dropped. Consider the DataFrame as an alternative that allows one to specify row names.

## Coercion

as (from, "DataFrame"): By default, constructs a new DataFrame with from as its only column. If from is a matrix or data. frame, all of its columns become columns in the new DataFrame. If from is a list, each element becomes a column, recycling as necessary. Note that for the DataFrame to behave correctly, each column object must support elementwise subsetting via the [ method and return the number of elements with length. It is recommended to use the DataFrame constructor, rather than this interface.

```
as.list(x): Coerces x, a DataFrame, to a list.
```

as.data.frame(x, row.names=NULL, optional=FALSE):Coerces x, aDataFrame, to a data.frame. Each column is coerced to a data.frame and then column bound together. If row. names is NULL, they are retrieved from x , if it has any. Otherwise, they are inferred by the data. frame constructor.
NOTE: conversion of x to a data. frame is not supported if x contains any list, SimpleList, or CompressedList columns.
as (from, "data.frame"): Coerces a DataFrame to a data.frame by calling as.data.frame (from).

```

```
DataFrameList-class
```

    List of DataFrames
    
## Description

Represents a list of DataFrame objects. The SplitDataFrameList class contains the additional restriction that all the columns be of the same name and type. Internally it is stored as a list of DataFrame objects and extends Sequence.

## Accessors

In the following code snippets, x is a DataFrameList.
$\operatorname{dim}(x)$ : Get the two element integer vector indicating the number of rows and columns over the entire dataset.
dimnames $(\mathrm{x})$ : Get the list of two character vectors, the first holding the rownames (possibly NULL) and the second the column names.
columnMetadata (x): Get the DataFrame of metadata along the columns, i.e., where each column in $x$ is represented by a row in the metadata. The metadata is common across all elements of $x$. Note that calling elementMetadata $(x)$ returns the metadata on the DataFrame elements of $x$. columnMetadata (x) <- value: Set the DataFrame of metadata for the columns.

## Subsetting

In the following code snippets, x is a SplitDataFrameList. In general x follows the conventions of SimpleList/CompressedList with the following addition:
$x[i, j, d r o p]$ : If matrix subsetting is used, i selects either the list elements or the rows within the list elements as determined by the [ method for SimpleList/CompressedList, codej selects the columns, and drop is used when one column is selected and output can be coerced into an AtomicList or RangesList subclass.
$x[i, j]<-$ value: If matrix subsetting is used, $i$ selects either the list elements or the rows within the list elements as determined by the [<- method for SimpleList/CompressedList, $j$ selects the columns and value is the replacement value for the selected region.

## Constructor

DataFrameList (...): Concatenates the DataFrame objects in . . . into a new DataFrameList.
SplitDataFrameList(..., compress = TRUE, cbindArgs = FALSE):If cbindArgs is FALSE, the . . . arguments are coerced to DataFrame objects and concatenated to form the result. The arguments must have the same number and names of columns. If cbindArgs is TRUE, the arguments are combined as columns. The arguments must then be the same length, with each element of an argument mapping to an element in the result. If compress = TRUE, returns a CompressedSplitDataFrameList; else returns a SimpleSplitDataFrameList.

## Combining

In the following code snippets, objects in . . . are of class DataFrameList.
rbind(...): Creates a new DataFrameList containing the element-by-element row concatenation of the objects in . . . .
cbind(...): Creates a new DataFrameList containing the element-by-element column concatenation of the objects in . . .

## Coercion

In the following code snippets, x is a DataFrameList.
as (from, "DataFrame"): Coerces a DataFrameList to an DataFrame by combining the rows of the elements. This essentially unsplits the DataFrame. Every element of x must have the same columns.
as (from, "SplitDataFrameList"): By default, simply calls the SplitDataFrameList constructor on from. If from is a Sequence, each element of from is passed as an argument to SplitDataFrameList, like calling as.list on a vector
as.data.frame (x, row.names=NULL, optional=FALSE, ...): Unsplits the DataFrame and coerces it to a data.frame, with the rownames specified in row. names. The optional argument is ignored.
stack(x, indName = "space"): Unlists x and adds a column named indName to the result, indicating the element of x from which each row was obtained.

DataFrame, RangedData, which uses a DataFrameList to split the data by the spaces.

```
DataTable-class DataTable objects
```

## Description

The DataTable virtual class provides an interface for the storing rectangular data sets, like a basic data.frame object. It extends Sequence.

## Accessors

In the following code snippets, x is a DataTable.
nrow (x), ncol (x): Get the number of rows and columns, respectively.
NROW (x), NCOL (x): Same as nrow (x) and ncol (x), respectively.
dim (x): Length two integer vector defined as $c(n r o w(x), ~ n c o l(x))$.
rownames (x), colnames (x): Get the names of the rows and columns, respectively.
dimnames (x): Length two list of character vectors defined as list (rownames(x), colnames(x)).

## Subsetting

In the code snippets below, x is a DataTable object.
x[i, j, drop=TRUE]:Return a new DataTable object made of the selected rows and columns. For single column selection, the drop argument specifies whether or not to coerce the returned sequence to a standard vector.
window (x, start $=$ NA, end $=N A$, width $=$ NA, frequency $=$ NULL, delta = NULL, . . .) : Extract the subsequence window from the DataTable object using: start, end, width The start, end, or width of the window. Two of the three are required. frequency, delta Optional arguments that specify the sampling frequency and increment within the window.

In general, this is more efficient than using " [ " operator.
window (x, start = NA, end = NA, width = NA, keepLength = TRUE) <- value: Replace the subsequence window specified on the left (i.e. the subsequence in $x$ specified by start, end and width) by value. value must either be of class class (x), belong to a subclass of class ( $x$ ), be coercible to class ( $x$ ), or be NULL. If keepLength is TRUE, the number of rows of value are repeated to create a DataTable with the same number of rows as the width of the subsequence window it is replacing. If keepLength is FALSE, this replacement method can modify the number of rows of $x$, depending on how the number of rows of the left subsequence window compares to the number of rows of value.
seqselect (x, start=NULL, end=NULL, width=NULL): Similar to window, except that multiple subsequences can be requested. The requested subsequences are concatenated.

```
seqselect(x, start=NULL, end=NULL, width=NULL) <- value: Similartowindow<-
``` , except that multiple consecutive subsequences can be replaced by a value that spans those windows.
head ( \(\mathrm{x}, \mathrm{n}=6 \mathrm{~L}\) ): If n is non-negative, returns the first n rows of the DataTable object. If n is negative, returns all but the last \(\mathrm{abs}(\mathrm{n})\) rows of the DataTable object.
tail ( \(\mathrm{x}, \mathrm{n}=6 \mathrm{~L}\) ): If n is non-negative, returns the last n rows of the DataTable object. If n is negative, returns all but the first abs ( n ) rows of the DataTable object.
subset ( \(x\), subset, select, drop = FALSE) : Return a new DataTable object using:
subset logical expression indicating rows to keep, where missing values are taken as FALSE.
select expression indicating columns to keep.
drop passed on to [ indexing operator.
na. omit (object): Returns a subset with incomplete cases removed.
na.exclude (object) : Returns a subset with incomplete cases removed (but to be included with NAs in statistical results).
is. na \((x)\) : Returns a logical matrix indicating which cells are missing.
complete.cases (x) : Returns a logical vector identifying which cases have no missing values.

\section*{Combining}

In the code snippets below, x is a DataTable object.
cbind (...): Creates a new DataTable by combining the columns of the DataTable objects in . . .
rbind (...): Creates a new DataTable by combining the rows of the DataTable objects in . . .

\section*{Looping}

In the code snippets below, x is a DataTable object.
aggregate(x, by, FUN, start = NULL, end = NULL, width = NULL, frequency
\(=\) NULL, delta \(=\) NULL,..., simplify \(=\) TRUE)): Generates summaries on
the specified windows and returns the result in a convenient form:
by An object with start, end, and width methods.
FUN The function, found via match. fun, to be applied to each window of x .
start, end, width the start, end, or width of the window. If by is missing, then must supply two of the three.
frequency, delta Optional arguments that specify the sampling frequency and increment within the window.
... Further arguments for FUN.
simplify A logical value specifying whether or not the result should be simplified to a vector or matrix if possible.
by (data, INDICES, FUN, ..., simplify = TRUE): Apply FUN to each group of data, a DataTable, formed by the factor (or list of factors) INDICES. Exactly the same contract as as.data.frame.

\section*{Coercion}
as.env(x, enclos = parent.frame()): Creates an environment from \(x\) with a symbol for each colnames ( x ). The values are not actually copied into the environment. Rather, they are dynamically bound using makeActiveBinding. This prevents unnecessary copying of the data from the external vectors into \(R\) vectors. The values are cached, so that the data is not copied every time the symbol is accessed.

```

FilterRules-class Collection of Filter Rules

\section*{Description}

A FilterRules object is a collection of filter rules, which can be either expression or function objects. Rules can be disabled/enabled individually, facilitating experimenting with different combinations of filters.

\section*{Details}

It is common to split a dataset into subsets during data analysis. When data is large, however, representing subsets (e.g. by logical vectors) and storing them as copies might become too costly in terms of space. The FilterRules class represents subsets as lightweight expression and/or function objects. Subsets can then be calculated when needed (on the fly). This avoids copying and storing a large number of subsets. Although it might take longer to frequently recalculate a subset, it often is a relatively fast operation and the space savings tend to be more than worth it when data is large.

Rules may be either expressions or functions. Evaluating an expression or invoking a function should result in a logical vector. Expressions are often more convenient, but functions (i.e. closures)
are generally safer and more powerful, because the user can specify the enclosing environment. If a rule is an expression, it is evaluated inside the envir argument to the eval method (see below). If a function, it is invoked with envir as its only argument. See examples.

\section*{Accessor methods}

In the code snippets below, x is a RangedDat a object.
active ( \(x\) ): Get the logical vector of length length (x), where TRUE for an element indicates that the corresponding rule in \(x\) is active (and inactive otherwise). Note that names (active ( \(x\) ) ) is equal to names ( \(x\) ).
active ( \(x\) ) <- value: Replace the active state of the filter rules. If value is a logical vector, it should be of length length ( x ) and indicate which rules are active. Otherwise, it can be either numeric or character vector, in which case it sets the indicated rules (after dropping NA's) to active and all others to inactive. See examples.

\section*{Constructor}
```

FilterRules(exprs = list(), ..., active = TRUE):ConstructsaFilterRules

``` with the rules given in the list exprs or in . . . The initial active state of the rules is given by active, which is recycled as necessary. Elements in exprs may be either character (parsed into an expression), a language object (coerced to an expression), an expression, or a function that takes at least one argument. IMPORTANTLY, all arguments in . . . are quote ()'d and then coerced to an expression. So, for example, character data is only parsed if it is a literal. The names of the filters are taken from the names of exprs and . . ., if given. Otherwise, the character vectors take themselves as their name and the others are deparsed (before any coercion). Thus, it is recommended to always specify meaningful names. In any case, the names are made valid and unique.

\section*{Subsetting and Replacement}

In the code snippets below, x is a FilterRules object.
\(\mathrm{x}[\mathrm{i}]\) : Subsets the filter rules using the same interface as for Sequence.
x[[i]]: Extracts an expression or function via the same interface as for Sequence.
\(x[[i]]\) <- value: The same interface as for Sequence. The default active state for new rules is TRUE.

\section*{Combining}

In the code snippets below, x is a FilterRules object.
append(x, values, after = length(x)):Appends the values FilterRules instance onto \(x\) at the index given by after.
\(c(x, \ldots\), recursive \(=\) FALSE \():\) Concatenates the FilterRule instances in.. . onto the end of \(x\).

\section*{Evaluating}
eval(expr, envir = parent.frame(), enclos = if (is.list(envir) || is.pairlist(e parent.frame() else baseenv()): Evaluates a FilterRules instance (passed as the expr argument). Expression rules are evaluated in envir, while function rules are invoked with envir as their only argument. The evaluation of a rule should yield a logical
vector. The results from the rule evaluations are combined via the AND operation (i.e. \&) so that a single logical vector is returned from eval.

\section*{Author(s)}

Michael Lawrence

\section*{See Also}
rdapply, which accepts a FilterRules instance to filter each space before invoking the user function.

\section*{Examples}
```

## constructing a FilterRules instance

## an empty set of filters

filters <- FilterRules()

## as a simple character vector

filts <- c("peaks", "promoters")
filters <- FilterRules(filts)
active(filters) \# all TRUE

## with functions and expressions

filts <- list(peaks = expression(peaks), promoters = expression(promoters),
find_eboxes = function(rd) rep(FALSE, nrow(rd)))
filters <- FilterRules(filts, active = FALSE)
active(filters) \# all FALSE

## direct, quoted args (character literal parsed)

filters <- FilterRules(under_peaks = peaks, in_promoters = "promoters")
filts <- list(under_peaks = expression(peaks),
in_promoters = expression(promoters))

## specify both exprs and additional args

filters <- FilterRules(filts, diffexp = de)
filts <- c("peaks", "promoters", "introns")
filters <- FilterRules(filts)

## set the active state directly

active(filters) <- FALSE \# all FALSE
active(filters) <- TRUE \# all TRUE
active(filters) <- c(FALSE, FALSE, TRUE)
active(filters)["promoters"] <- TRUE \# use a filter name

## toggle the active state by name or index

active(filters) <- c(NA, 2) \# NA's are dropped
active(filters) <- c("peaks", NA)

```

GappedRanges-class GappedRanges objects

\section*{Description}

The GappedRanges class is a vector-like container for storing a set of "gapped ranges".

\section*{Details}

A "gapped range" is conceptually the union of 1 or more non-overlapping (and non-empty) ranges ordered from left to right. More precisely, a "gapped range" can be represented by a normal IRanges object of length \(>=1\). In particular normality here ensures that the individual ranges are non-empty and are separated by non-empty gaps. The start of a "gapped range" is the start of its first range. The end of a "gapped range" is the end of its last range. If we ignore the gaps, then a GappedRanges object can be seen as a Ranges object.

\section*{Constructor}

No constructor function is provided for GappedRanges objects. The coercion methods described below can be used to create GappedRanges objects.

\section*{Coercion}
as (from, "GappedRanges"): Turns a CompressedNormalIRangesList or CompressedIRangesList object into a GappedRanges object.
as (from, "RangesList"): Turns a GappedRanges object into a RangesList object (more precisely the result will be a CompressedNormalIRangesList object).

\section*{Accessor methods}

In the code snippets below, x is a GappedRanges object.
length \((x)\) : Returns the number of "gapped ranges" in \(x\).
start (x), end (x): Returns an integer vector of length length \((x)\) containing the start and end (respectively) of each "gapped range" in \(x\). See Details section above for the exact definitions of the start and end of a "gapped range".
width (x): Defined as end (x) - start (x) + 1L.
ngap \((x)\) : Returns an integer vector of length length \((x)\) containing the number of gaps for each "gapped range" in \(x\). Equivalent to elementLengths (x) - 1L.
names ( \(x\) ): NULL or a character vector of length length ( \(x\) ).

\section*{Subsetting and related operations}

In the code snippets below, x is a GappedRanges object.
x[i]: Returns a new GappedRanges object made of the selected "gapped ranges". i can be a numeric, character or logical vector, or any of the types supported by the [ method for CompressedNormalIRangesList objects.
\(x[\) [i] ]: Returns the NormalIRanges object representing the i-th element in \(x\). Equivalent to as (from, "RangesList") [[i]]. i can be a single numeric value or a single character string.
elemenType (x): Returns the type of \(x\) [ [i] ] as a single string (always "NormaliRanges").
Note that the semantic of the [ [ method for GappedRanges objects is different from the semantic of the method for Ranges objects (the latter returns an integer vector).
elementLengths (x): Semantically equivalent to
sapply(seq_len(length(x)), function(i) length(x[[i]]))
but much faster. Note that the semantic of the elementLengths method for GappedRanges objects is different from the semantic of the method for Ranges objects (the latter returns the width of the Ranges object).

\section*{Combining and related operations}

In the code snippets below, x is a GappedRanges object.
\(\mathrm{c}(\mathrm{x}, \ldots, \ldots)\) : Combine x and the GappedRanges objects in . . . together. The result is an object of the same class as \(x\).

\section*{Description}

In this man page, we call "grouping" the action of dividing a collection of NO objects into NG groups (some of which may be empty). The Grouping class and subclasses are containers for representing groupings.

\section*{The Grouping core API}

Let's give a formal description of the Grouping core API:
Groups G_i are indexed from 1 to \(\mathrm{NG}(1<=\mathrm{i}<=\mathrm{NG})\).
Objects O_j are indexed from 1 to \(\mathrm{NO}(1<=\mathrm{j}<=\mathrm{NO})\).
Every object must belong to one group and only one.
Given that empty groups are allowed, NG can be greater than NO.
Grouping an empty collection of objects \((\mathrm{NO}=0)\) is supported. In that case, all the groups are empty. And only in that case, NG can be zero too (meaning there are no groups).

If \(x\) is a Grouping object:
length (x) : Returns the number of groups (NG).
names ( \(x\) ) : Returns the names of the groups.
nobj \((x)\) : Returns the number of objects (NO). Equivalent to length (togroup (x)).
Going from groups to objects:
\(\mathrm{x}[\mathrm{i}]]\) : Returns the indices of the objects (the j's) that belong to G_i. The j's are returned in ascending order. This provides the mapping from groups to objects (one-to-many mapping).
grouplength (x, i=NULL) : Returns the number of objects in G_i. Works in a vectorized fashion (unlike \(x[\) [i] ]). grouplength (x) is equivalent to grouplength (x, seq_len(length(x))) If \(i\) is not NULL, grouplength ( \(x, i\) ) is equivalent to sapply (i, function(ii) length(x[[ii]])).
 vector of arbitrary length, it's equivalent to sort (unlist (sapply (i, function(ii) x[[ii]]))).
vmembers ( \(\mathrm{x}, \mathrm{L}\) ): A version of members that works in a vectorized fashion with respect to the \(L\) argument ( \(L\) must be a list of integer vectors). Returns lapply ( \(L\), function(i) members(x, i)).

Going from objects to groups:
togroup ( \(\mathrm{x}, \mathrm{j}=\mathrm{NULL}\) ): Returns the index i of the group that \(\mathrm{O}_{-} \mathrm{j}\) belongs to. This provides the mapping from objects to groups (many-to-one mapping). Works in a vectorized fashion. togroup (x) is equivalent to togroup (x, seq_len(nobj(x))): both return the entire mapping in an integer vector of length NO. If \(j\) is not NULL, togroup \((x, j)\) is equivalent to \(y<-\) togroup (x); y[j].
togrouplength ( \(x, j=N U L L\) ) : Returns the number of objects that belong to the same group as \(O_{-} \mathfrak{j}\) (including \(O_{\mathrm{J}} \mathrm{j}\) itself). Equivalent to grouplength ( \(\mathrm{x}, \operatorname{togroup}(\mathrm{x}, \mathrm{j})\) ).

Given that length, names and [ [ are defined for Grouping objects, those objects can be considered Sequence objects. In particular, as.list works out-of-the-box on them.

One important property of any Grouping object \(x\) is that unlist(as.list(x)) is always a permutation of seq_len (nobj (x)). This is a direct consequence of the fact that every object in the grouping belongs to one group and only one.

\section*{The H2LGrouping and Dups subclasses}

\section*{DOCUMENT ME}

\section*{The Partitioning subclass}

A Partitioning container represents a block-grouping, i.e. a grouping where each group contains objects that are neighbors in the original collection of objects. More formally, a grouping x is a block-grouping iff togroup ( \(x\) ) is sorted in increasing order (not necessarily strictly increasing).

A block-grouping object can also be seen (and manipulated) as a Ranges object where all the ranges are adjacent starting at 1 (i.e. it covers the \(1: \mathrm{NO}\) interval with no overlap between the ranges).
Note that a Partitioning object is both: a particular type of Grouping object and a particular type of Ranges object. Therefore all the methods that are defined for Grouping and Ranges objects can also be used on a Partitioning object. See ?Ranges for a description of the Ranges API.
The Partitioning class is virtual with 2 concrete subclasses: PartitioningByEnd (only stores the end of the groups, allowing fast mapping from groups to objects), and PartitioningByWidth (only stores the width of the groups).

\section*{Binning subclass}

A Binning container represents a grouping where each observation is assigned to a group or bin. It is similar in nature to taking a the integer codes of a factor object and splitting it up by its levels (i.e. myFactor \(<-\) factor(...); split(as.integer(myFactor), myFactor)).

\section*{Constructors}

\section*{H2LGrouping (high2low=integer()): [DOCUMENT ME]}

Dups (high2low=integer()): [DOCUMENT ME]
PartitioningByEnd (end=integer(), names=NULL): Return the PartitioningByEnd object made of the partitions ending at the values specified by end. end must contain sorted non-negative integer values. If the names argument is non NULL, it is used to name the partitions.
PartitioningByWidth(width=integer(), names=NULL): Return the PartitioningByWidth object made of the partitions with the widths specified by width. width must contain non-negative integer values. If the names argument is non NULL, it is used to name the partitions.
Binning(group=integer(), names=NULL): Return the Binning object made from the group argument, which takes a factor or positive valued integer vector. If the names argument is non NULL, it is used to name the bins. When group is a factor, the names are set to levels (group) unless specified otherwise.
Note that these constructors don't recycle their names argument (to remain consistent with what 'names<- ' does on standard vectors).

IRanges-class IRanges and NormalIRanges objects

\section*{Description}

The IRanges class is a simple implementation of the Ranges container where 2 integer vectors of the same length are used to store the start and width values. See the Ranges virtual class for a formal definition of Ranges objects and for their methods (all of them should work for IRanges objects).

Some subclasses of the IRanges class are: NormalIRanges, Views, etc...
A NormalIRanges object is just an IRanges object that is guaranteed to be "normal". See the Normality section in the man page for Ranges objects for the definition and properties of "normal" Ranges objects.

\section*{Constructor}

See ¿IRanges-constructor \({ }^{`}\).

\section*{Coercion}
as (from, "IRanges"): Creates an IRanges instance from a Ranges object, logical vector, or integer vector. When from is a logical vector, the resulting IRanges object contains the indices for the runs of TRUE values. When from is an integer vector, the elements are either singletons or "increase by 1 " sequences.
as (from, "NormalIRanges"): Creates a NormalIRanges instance from a logical or integer vector. When from is an integer vector, the elements must be strictly increasing.

\section*{Methods for NormalIRanges objects}
\(\max (x)\) : The maximum value in the finite set of integers represented by \(x\).
\(\min (x)\) : The minimum value in the finite set of integers represented by \(x\).

\section*{Author(s)}
H. Pages

\section*{See Also}

Some direct subclasses of the IRanges class (other than NormalIRanges): Views-class.

\section*{Examples}
```

showClass("IRanges") \# shows (some of) the known subclasses

## -------------------------------------------------------------------------------

## A. MANIPULATING IRanges OBJECTS

## ----------------------------------------------------------------------------

## All the methods defined for Ranges objects work on IRanges objects.

## See ?Ranges for some examples.

## Also see ?`IRanges-utils` and ?`IRanges-setops` for additional

## operations on IRanges objects.

## -----------------------------------------------------------------------------

## B. A NOTE ABOUT PERFORMANCE

## ----------------------------------------------------------------------------

## Using an IRanges object for storing a big set of ranges is more

## efficient than using a standard R data frame:

N <- 2000000L \# nb of ranges
W <- 180L \# width of each range
start <- 1L
end <- 50000000L
set.seed(777)
range_starts <- sort(sample(end-W+1L, N))
range_widths <- rep.int(W, N)

## Instantiation is faster

system.time(x <- IRanges(start=range_starts, width=range_widths))
system.time(y <- data.frame(start=range_starts, width=range_widths))

## Subsetting is faster

system.time(x16 <- x[c(TRUE, rep.int(FALSE, 15))])
system.time(y16 <- y[c(TRUE, rep.int(FALSE, 15)), ])

## Internal representation is more compact

object.size(x16)
object.size(y16)

```
```

IRanges-constructor

```

The IRanges constructor and supporting functions

\section*{Description}

The IRanges function is a constructor that can be used to create IRanges instances.
solveUserSEWO and solveUserSEW are utility functions that solve a set of user-supplied start/end/width values.

\section*{Usage}
```

## IRanges constructor:

IRanges(start=NULL, end=NULL, width=NULL, names=NULL)

## Supporting functions (not for the end user):

solveUserSEWO(start=NULL, end=NULL, width=NULL)
solveUserSEW(refwidths, start=NA, end=NA, width=NA,
rep.refwidths=FALSE,
translate.negative.coord=TRUE,
allow.nonnarrowing=FALSE)

```

\section*{Arguments}
```

start, end, width
For IRanges and solveUserSEW0: NULL, or vector of integers (eventually
with NAs).
For solveUserSEW: vector of integers (eventually with NAs).
names A character vector or NULL.
refwidths Vector of non-NA non-negative integers containing the reference widths.
rep.refwidths
TRUE or FALSE. Use of rep.refwidths=TRUE is supported only when
refwidths is of length 1.
translate.negative.coord, allow.nonnarrowing
TRUE or FALSE.

```

\section*{IRanges constructor}

Return the IRanges object containing the ranges specified by start, end and width. Input falls into one of two categories:

Category 1 start, end and width are numeric vectors (or NULLs). If necessary they are recycled to the length of the longest (NULL arguments are filled with NAs). After this recycling, each row in the 3-column matrix obtained by binding those 3 vectors together is "solved" i.e. NAs are treated as unknown in the equation end \(=\) start + width -1 . Finally, the solved matrix is returned as an IRanges instance.
Category 2 The start argument is a logical vector or logical Rle object and IRanges (start) produces the same result as as (start, "IRanges"). Note that, in that case, the returned IRanges instance is guaranteed to be normal.

Note that the names argument is never recycled (to remain consistent with what 'names<- ' does on standard vectors).

\section*{Supporting functions}
```

solveUserSEWO(start=NULL, end=NULL, width=NULL):

```
solveUserSEW(refwidths, start=NA, end=NA, width=NA, rep.refwidths=FALSE,
    translate.negative.coord=TRUE, allow.nonnarrowing=FALSE): Use of rep.refwidths=T
    is supported only when refwidths is of length 1. If rep. refwidths=FALSE (the de-
    fault) then start, end and width are recycled to the length of refwidths (it's an error
    if one of them is longer than refwidths, or is of zero length while refwidths is not). If
    rep.refwidths=TRUE then refwidths is first replicated \(L\) times where \(L\) is the length
    of the longest of start, end and width. After this replication, start, end and width
    are recycled to the new length of refwidths (L) (it's an error if one of them is of zero length
    while L is \(!=0\) ).
    From now, refwidths, start, end and width are integer vectors of equal lengths. Each
    row in the 3 -column matrix obtained by binding those 3 vectors together must contain at least
    one NA (otherwise an error is returned). Then each row is "solved" i.e. the 2 following trans-
    formations are performed ( \(i\) is the indice of the row): (1) if translate. negative. coord
    is TRUE then a negative value of start [i] or end [i] is considered to be a-refwidths [i]-
    based coordinate so refwidths [i]+1 is added to it to make it 1-based; (2) the NAs in the
    row are treated as unknowns which values are deduced from the known values in the row and
    from refwidths[i].

The exact rules for (2) are the following. Rule (2a): if the row contains at least 2 NAs, then width [i] must be one of them (otherwise an error is returned), and if start [i] is one of
them it is replaced by 1 , and if end [i] is one of them it is replaced by refwidths [i], and finally width[i] is replaced by end[i] - start[i] + 1. Rule (2b): if the row contains only 1 NA , then it is replaced by the solution of the width [i] == end[i] start[i] + 1 equation.
Finally, the set of solved rows is returned as an IRanges object of the same length as refwidths (after replication if rep.refwidths=TRUE).
Note that an error is raised if either (1) the set of user-supplied start/end/width values is invalid or (2) allow. nonnarrowing is FALSE and the ranges represented by the solved start/end/width values are not narrowing the ranges represented by the user-supplied start/end/width values.

solveUserSEW(refwidths, end=-4)

## The start/end/width arguments are recycled:

solveUserSEW(refwidths, start=c(3, -4, NA), end=c(-2, NA))

## Using 'rep.refwidths=TRUE':

solveUserSEW(10, start=-(1:6), rep.refwidths=TRUE)
solveUserSEW(10, end=-(1:6), width=3, rep.refwidths=TRUE)

```

\section*{Description}

Performs set operations on IRanges objects.
```

Usage
\#\# Vector-wise operations:
gaps(x, start=NA, end=NA)
\#\# S4 method for signature 'IRanges,IRanges':
union(x, y)
\#\# S4 method for signature 'IRanges,IRanges':
intersect(x, y)
\#\# S4 method for signature 'IRanges,IRanges':
setdiff(x, y)
\#\# Element-wise (aka "parallel") operations:
\#\# S4 method for signature 'IRanges,IRanges':
punion(x, y, fill.gap=FALSE, ...)
\#\# S4 method for signature 'IRanges,IRanges':
pintersect(x, y, resolve.empty=c("none", "max.start", "start.x"), ...)
\#\# S4 method for signature 'IRanges,IRanges':
psetdiff(x, y, ...)
\#\# S4 method for signature 'IRanges,IRanges':
pgap(x, y, ...)

```

\section*{Arguments}
\(\mathrm{x}, \mathrm{y} \quad\) IRanges objects.
start, end A single integer or NA. Use these arguments to specify the interval of reference i.e. which interval the returned gaps should be relative to.
fill.gap Logical indicating whether or not to force a union by using the rule start \(=\) min(start(x), start(y)), end = max (end(x), end(y)).
resolve.empty
One of "none", "max.start", or "start.x" denoting how to handle ambiguous empty ranges formed by intersections. "none" - throw an error if an ambiguous empty range is formed, "max.start" - associate the maximum start value with any ambiguous empty range, and "start.x" - associate the start value of x with any ambiguous empty range. (See Details section below for the definition of an ambiguous range.)
. . . Further arguments to be passed to or from other methods.

\section*{Details}
gaps returns the "normal" IRanges object (of the same class as x ) representing the set of integers that remain after the set of integers represented by \(x\) has been removed from the interval specified by the start and end arguments.

The union, intersect and setdiff methods for IRanges objects return a "normal" IRanges object (of the same class as \(x\) ) representing the union, intersection and (asymmetric!) difference of the sets of integers represented by \(x\) and \(y\).
punion, pintersect, psetdiff and pgap are generic functions that compute the elementwise (aka "parallel") union, intersection, (asymmetric!) difference and gap between each element in \(x\) and its corresponding element in \(y\). Methods for IRanges objects are defined. For these methods, \(x\) and \(y\) must have the same length (i.e. same number of ranges) and they return an IRanges instance of the same length as \(x\) and \(y\) where each range represents the union/intersection/difference/gap of/between the corresponding ranges in x and y .

By default, pintersect will throw an error when an "ambiguous empty range" is formed. An ambiguous empty range can occur three different ways: 1) when corresponding non-empty ranges elements \(x\) and \(y\) have an empty intersection, 2) if the position of an empty range element does not fall within the corresponding limits of a non-empty range element, or 3 ) if two corresponding empty range elements do not have the same position. For example if empty range element [22,21] is intersected with non-empty range element [1,10], an error will be produced; but if it is intersected with the range [22,28], it will produce [22,21]. As mentioned in the Arguments section above, this behavior can be changed using the resolve. empty argument.

\section*{Author(s)}
H. Pages and M. Lawrence

\section*{See Also}
pintersect is similar to narrow, except the end points are absolute, not relative. pintersect is also similar to restrict, except ranges outside of the restriction become empty and are not discarded. union, intersect, setdiff, Ranges-class, Ranges-utils, IRanges-class, IRanges-utils

\section*{Examples}
```

x0<- IRanges(start=c(-2, 6, 9, -4, 1, 0, -6, 10),
width=c(5, 0, 6, 1, 4, 3, 2, 3))
gaps (x0)
gaps(x0, start = - 6, end=20) \# Regions of the -6:20 range that are not masked by 'x0'.
x <- IRanges (c(1, 5, -2, 0, 14), c(10, 9, 3, 11, 17))
y<- Views(as(4:-17, "XInteger"), start=c(14, 0, -5, 6, 18), end=c(20, 2, 2, 8, 20))

## Vector-wise operations:

union(x, y)
union(y, x)
intersect(x, y)
intersect(y, x)
setdiff(x, y)
setdiff(y, x)

## Element-wise (aka "parallel") operations:

try(punion(x, y))
punion(x[3:5], y[3:5])
punion(x, y, fill.gap=TRUE)
try(pintersect(x, y))

```
```

pintersect(x[3:4], y[3:4])
pintersect(x, y, resolve.empty="max.start")
psetdiff(y, x)
try(psetdiff(x, y))
start(x)[4] <- -99
end(y)[4] <- 99
psetdiff(x, y)
pgap(x, y)

```

IRanges-utils IRanges utility functions

\section*{Description}

Utility functions for creating or modifying IRanges objects.

\section*{Usage}
\#\# Create an IRanges instance: successiveIRanges(width, gapwidth=0, from=1)
```

## Turn a logical vector into a set of ranges:

```
whichAsIRanges(x)
\#\# Coercion:
asNormalIRanges(x, force=TRUE)

\section*{Arguments}
width A vector of non-negative integers (with no NAs) specifying the widths of the ranges to create.
gapwidth A single integer or an integer vector with one less element than the width vector specifying the widths of the gaps separating one range from the next one.
from A single integer specifying the starting position of the first range.
\(x \quad\) A logical vector for whichAsIRanges. An IRanges object for asNormal IRanges.
force TRUE or FALSE. Should \(x\) be turned into a NormalIRanges object even if isNormal ( x ) is FALSE?

\section*{Details}
successiveIRanges returns an IRanges instance containing the ranges that have the widths specified in the width vector and are separated by the gaps specified in gapwidth. The first range starts at position from. When gapwidth=0 and from=1 (the defaults), the returned IRanges can be seen as a partitioning of the 1 :sum(width) interval. See ?Partitioning for more details on this.
whichAsIRanges returns an IRanges instance containing all of the ranges where x is TRUE.
If force=TRUE (the default), then asNormalIRanges will turn x into a NormalIRanges instance by reordering and reducing the set of ranges if necessary (i.e. only if isNormal (x) is FALSE, otherwise the set of ranges will be untouched). If force=FALSE, then asNormalIRanges will turn \(x\) into a NormalIRanges instance only if isNormal ( \(x\) ) is TRUE, otherwise it will raise
an error. Note that when force=FALSE, the returned object is guaranteed to contain exactly the same set of ranges than x . as ( x , "NormalIRanges") is equivalent to asNormalIRanges ( x , force=TRUE).

\section*{IRangesList-class List of IRanges and NormalIRanges}

\section*{Description}

IRangesList and NormalIRangesList objects for storing IRanges and NormalIRanges objects respectively.

\section*{Constructor}

IRangesList(..., universe = NULL, compress = TRUE): The ... argument accepts either a comma-separated list of IRanges objects, or a single LogicalList / logical RleList object, or 2 elements named start and end each of them being either a list of integer vectors or an IntegerList object. When IRanges objects are supplied, each of them becomes an element in the new IRangesList, in the same order, which is analogous to the list constructor. If compress, the internal storage of the data is compressed.

\section*{Coercion}
unlist(x): Unlists x , an IRangesList, by concatenating all of the ranges into a single IRanges instance. If the length of \(x\) is zero, an empty IRanges is returned.

\section*{Methods for NormalIRangesList objects}
\(\max (x)\) : An integer vector containing the maximum values of each of the elements of \(x\).
\(\min (x)\) : An integer vector containing the minimum values of each of the elements of \(x\).

RangesList, the parent of this class, for more functionality.

\section*{Examples}
```

range1 <- IRanges(start=c(1,2,3), end=c(5,2,8))
range2 <- IRanges(start=c(15,45,20,1), end=c(15,100,80,5))
named <- IRangesList(one = range1, two = range2)
length(named) \# 2
names(named) \# "one" and "two"
named[[1]] \# range1
unnamed <- IRangesList(range1, range2)
names(unnamed) \# NULL
x <- IRangesList(start=list(c(1,2,3), c(15,45,20,1)),
end=list(c(5,2,8), c(15,100,80,5)))
as.list(x)

```

IntervalTree-class Interval Search Trees

\section*{Description}

Efficiently perform overlap queries with an interval tree.

\section*{Details}

A common type of query that arises when working with intervals is finding which intervals in one set overlap those in another. An efficient family of algorithms for answering such queries is known as the Interval Tree. This implementation makes use of the augmented tree algorithm from the reference below, but heavily adapts it for the use case of large, sorted query sets.
The simplest approach is to call the findOverlaps function on a Ranges or other object with range information, as described in the following section.

An IntervalTree object is a derivative of Ranges and stores its ranges as a tree that is optimized for overlap queries. Thus, for repeated queries against the same subject, it is more efficient to create an IntervalTree once for the subject using the constructor described below and then perform the queries against the IntervalTree instance.

\section*{Finding Overlaps}

This main purpose of the interval tree is to optimize the search for ranges overlapping those in a query set. The interface for this operation is the findOverlaps function.
```

findOverlaps (query, subject = query, maxgap = 0L, minoverlap = 1L,
type = c("any", "start", "end", "within", "equal"), select = c("all",
"first", "last", "arbitrary"), drop = FALSE, ignoreSelf = FALSE,
ignoreRedundant = FALSE):

```
    Find the intervals in query, a Ranges, RangesList, RangedData, or integer vector
    (to be converted to length-one ranges), that overlap with the intervals subject, a Ranges,
    RangesList, or RangedData. If query is unsorted, it is sorted first, so it is usually better
    to sort up-front, to avoid a sort with each findOverlaps call.
    If subject is omitted, query is queried against itself. In this case, and only this case, the
    ignoreSelf and ignoreRedundant arguments are allowed. By default, the result will
    contain hits for each range against itself, and if there is a hit from \(A\) to \(B\), there is also a hit
    for B to A . If ignoreSelf is TRUE, all self matches are dropped. If ignoreRedundant
    is TRUE, only one of \(\mathrm{A}->\mathrm{B}\) and \(\mathrm{B}->\mathrm{A}\) is returned.

Intervals with a separation of maxgap or less and a minimum of minoverlap overlapping positions, allowing for maxgap, are considered to be overlapping. maxgap should be a scalar, non-negative, integer. minoverlap should be a scalar, positive integer.
When select is "all", the results are returned as a RangesMatching object. When select is "first", "last", or "arbitrary" the results are returned as an integer vector of length query containing the first, last, or arbitrary overlapping interval in subject, with NA indicating intervals that did not overlap any intervals in subject.
If query is a RangesList or RangedData, subject must be a RangesList or RangedData. If both lists have names, each element from the subject is paired with the element from the query with the matching name, if any. Otherwise, elements are paired by position. The overlap is then computed between the pairs as described above. If select is "all", a RangesMatchingList is returned. For all other select the return value depends on the drop argument. When select ! = "all" \&\& ! drop, an IntegerList is returned, where each element of the result corresponds to a space in query. Whenselect \(!=\) "all" \&\& drop, an integer vector is returned containing indices that are offset to align with the unlisted query.
By default, any overlap is accepted. By specifying the type parameter, one can select for specific types of overlap. The types correspond to operations in Allen's Interval Algebra (see references). If type is start or end, the intervals are required to have matching starts or ends, respectively. While this operation seems trivial, the naive implementation using outer would be much less efficient. Specifying equal as the type returns the intersection of the start and end matches. If type is within, the query interval must be wholly contained within the subject interval. Note that all matches must additionally satisfy the minoverlap constraint described above.
The maxgap parameter has special meaning with the special overlap types. For start, end, and equal, it specifies the maximum difference in the starts, ends or both, respectively. For within, it is the maximum amount by which the query may be wider than the subject.
countoverlaps (query, subject, maxgap \(=0 L\), minoverlap \(=1 L\), type \(=\) c("any", "start", "end", "within", "equal")): Returns the overlap hit count for each range in query using the specified findOverlaps parameters. Both query and subject should be Ranges, RangesList or RangedData objects.
subsetByOverlaps (query, subject, maxgap \(=0 L\), minoverlap \(=1 L\), type = c("any", "start", "end", "within", "equal")): Returns the subset of query that has an overlap hit with a range in sub ject using the specified findOverlaps
parameters. Both query and subject should be Ranges, RangesList or RangedData objects.
\(x\) \%in\% table: Shortcut for finding the ranges in \(x\) that overlap any of the ranges in table. Both \(x\) and table should be Ranges, RangesList or RangedData objects. For Ranges objects, the result is a logical vector of length equal to the number of ranges in x . For RangesList and RangedData objects, the result is a LogicalList object, where each element of the result corresponds to a space in \(x\).
match(x, table, nomatch = NA_integer_, incomparables = NULL):Returns an integer vector of length length \((x)\), containing the index of the first overlapping range in table for each range in \(x\). If a range in \(x\) does not overlap any ranges in table, its value is nomatch. The \(x\) and table arguments should either be both Ranges objects or both RangesList objects, in which case the indices are into the unlisted table. The incomparables argument is currently ignored.

\section*{Constructor}

IntervalTree(ranges): Creates an IntervalTree from the ranges in ranges, an object coercible to IntervalTree, such as an IRanges object.

\section*{Coercion}
as (from, "IRanges"): Imports the ranges in from, an IntervalTree, to an IRanges.
as (from, "IntervalTree"): Constructs an IntervalTree representing from, a Ranges object that is coercible to IRanges.

\section*{Accessors}
length (x): Gets the number of ranges stored in the tree. This is a fast operation that does not bring the ranges into R .
start (x): Get the starts of the ranges.
end \((x)\) : Get the ends of the ranges.

\section*{Notes on Time Complexity}

The cost of constructing an instance of the interval tree is a \(O(n * \lg (n))\), which makes it about as fast as other types of overlap query algorithms based on sorting. The good news is that the tree need only be built once per subject; this is useful in situations of frequent querying. Also, in this implementation the data is stored outside of R , avoiding needless copying. Of course, external storage is not always convenient, so it is possible to coerce the tree to an instance of IRanges (see the Coercion section).
For the query operation, the running time is based on the query size \(m\) and the average number of hits per query \(k\). The output size is then \(\max (m k, m)\), but we abbreviate this as mk. Note that when the multiple parameter is set to FALSE, \(k\) is fixed to 1 and drops out of this analysis. We also assume here that the query is sorted by start position (the findOverlaps function sorts the query if it is unsorted).

An upper bound for finding overlaps is \(O(\min (m k * \lg (n), n+m k))\). The fastest interval tree algorithm known is bounded by \(O(\min (m * \lg (n), n)+m k)\) but is a lot more complicated and involves two auxillary trees. The lower bound is Omega ( \(\lg (\mathrm{n})+\mathrm{mk}\) ), which is almost the same as for returning the answer, Omega ( mk ) . The average is of course somewhere in between.

This analysis informs the choice of which set of ranges to process into a tree, i.e. assigning one to be the subject and the other to be the query. Note that if \(m>n\), then the running time is \(O(m)\), and
the total operation of complexity \(O(n * l g(n)+m)\) is better than if \(m\) and \(n\) were exchanged. Thus, for once-off operations, it is often most efficient to choose the smaller set to become the tree (but k also affects this). This is reinforced by the realization that if mk is about the same in either direction, the running time depends only on n, which should be minimized. Even in cases where a tree has already been constructed for one of the sets, it can be more efficient to build a new tree when the existing tree of size \(n\) is much larger than the query set of size \(m\), roughly when \(n>\) \(m * \lg (n)\).

MaskCollection-class
MaskCollection objects

\section*{Description}

The MaskCollection class is a container for storing a collection of masks that can be used to mask regions in a sequence.

\section*{Details}

In the context of the Biostrings package, a mask is a set of regions in a sequence that need to be excluded from some computation. For example, when calling alphabetFrequency or matchPattern on a chromosome sequence, you might want to exclude some regions like the centromere or the repeat regions. This can be achieved by putting one or several masks on the sequence before calling alphabetFrequency on it.
A MaskCollection object is a vector-like object that represents such set of masks. Like standard \(R\) vectors, it has a "length" which is the number of masks contained in it. But unlike standard \(R\) vectors, it also has a "width" which determines the length of the sequences it can be "put on". For example, a MaskCollection object of width 20000 can only be put on an XString object of 20000 letters.

Each mask in a MaskCollection object x is just a finite set of integers that are >=1 and <= width (x). When "put on" a sequence, these integers indicate the positions of the letters to mask. Internally, each mask is represented by a NormalIRanges object.

\section*{Basic accessor methods}

In the code snippets below, x is a MaskCollection object.
length (x): The number of masks in \(x\).
width \((x)\) : The common with of all the masks in \(x\). This determines the length of the sequences that x can be "put on".
active (x): A logical vector of the same length as \(x\) where each element indicates whether the corresponding mask is active or not.
names \((x)\) : NULL or a character vector of the same length as \(x\).
desc (x): NULL or a character vector of the same length as \(x\).
nir_list( \(x\) ): A list of the same length as \(x\), where each element is a NormalIRanges object representing a mask in x .

\section*{Constructor}

Mask(mask.width, start=NULL, end=NULL, width=NULL): Return a single mask (i.e. a MaskCollection object of length 1 ) of width mask . width (a single integer \(>=1\) ) and masking the ranges of positions specified by start, end and width. See the IRanges constructor (?IRanges) for how start, end and width can be specified. Note that the returned mask is active and unnamed.

\section*{Other methods}

In the code snippets below, x is a MaskCollection object.
isEmpty (x): Return a logical vector of the same length as x , indicating, for each mask in x , whether it's empty or not.
\(\max (x)\) : The greatest (or last, or rightmost) masked position for each mask. This is a numeric vector of the same length as \(x\).
\(\min (x)\) : The smallest (or first, or leftmost) masked position for each mask. This is a numeric vector of the same length as \(x\).
maskedwidth (x): The number of masked position for each mask. This is an integer vector of the same length as x where all values are \(>=0\) and \(<=\) width ( x ).
maskedratio(x): maskedwidth(x) / width(x)

\section*{Subsetting and appending}

In the code snippets below, x and values are MaskCollection objects.
x[i]: Return a new MaskCollection object made of the selected masks. Subscript i can be a numeric, logical or character vector.
\(x[[i, ~ e x a c t=T R U E]]:\) Extract the mask selected by i as a NormalIRanges object. Subscript \(i\) can be a single integer or a character string.
append (x, values, after=length(x)): Add masks in values to \(x\).

\section*{Other methods}

In the code snippets below, x is a MaskCollection object. collapse \((x)\) : Return a MaskCollection object of length 1 obtained by collapsing all the active masks in x . gaps ( x ): Invert the masks in x .
subseq ( \(x\), start=NA, end=NA, width=NA): If \(y\) is a sequence that \(x\) has been put on top of, then subseq will return the set of submasks that go on top of the subsequence obtained by calling subseq on \(y\) (subseq must be called on \(x\) with the same arguments that have been used when called on \(y\) ).

rdapply
Applying over spaces

\section*{Description}

The rdapply function applies a user function over the spaces of a RangedData. The parameters to rdapply are collected into an instance of RDApplyParams, which is passed as the sole parameter to rdapply.

\section*{Usage}
```

rdapply(x, ...)

```

\section*{Arguments}

X
. . Additional arguments for methods

\section*{Details}

The rdapply function is an attempt to facilitate the common operation of performing the same operation over each space (e.g. chromosome) in a RangedData. To facilitate a wide array of such tasks, the function takes a large number of options. The RDApplyParams class is meant to help manage this complexity. In particular, it facilitates experimentation through its support for incremental changes to parameter settings.

There are two RangedDat a settings that are required: the user function object and the RangedData over which it is applied. The rest of the settings determine what is actually passed to the user function and how the return value is processed before relaying it to the user. The following is the description and rationale for each setting.
rangedData REQUIRED. The RangedData instance over which applyFun is applied.
applyFun REQUIRED. The user function to be applied to each space in the RangedData. The function must expect the RangedData as its first parameter and also accept the parameters specified in applyParams.
applyParams The list of additional parameters to pass to applyFun. Usually empty.
filterRules The instance of FilterRules that is used to filter each subset of the RangedData passed to the user function. This is an efficient and convenient means for performing the same operation over different subsets of the data on a space-by-space basis. In particular, this avoids the need to store subsets of the entire RangedData. A common workflow is to invoke rdapply with one set of active filters, enable different filters, reinvoke rdapply, and compare the results.
simplify A scalar logical (TRUE or FALSE) indicating whether the list to be returned from rdapply should be simplified as by sapply. Defaults to FALSE.
reducerFun The function that is used to convert the list that would otherwise be returned from rdapply to something more convenient. The function should take the list as its first parameter and also accept the parameters specified in reducerParams. This is an alternative to the primitive behavior of the simplify option (so simplify must be FALSE if this option is set). The aim is to orthogonalize the applyFun operation (i.e. the statistics) from the data structure of the result.
reducerParams A list of additional parameters to pass to reducerFun. Can only be set if reducerFun is set. Usually empty.

\section*{Value}

By default a list holding the result of each invocation of the user function, but see details.

\section*{Constructing an RDApplyParams object}

RDApplyParams (rangedData, applyFun, applyParams, filterRules, simplify, reducerFun, reducerParams): Constructs a RDApplyParams object with each setting specified by the argument of the same name. See the Details section for more information.

\section*{Accessors}

In the following code snippets, \(x\) is an RDApplyParams object.
rangedData (x), rangedData(x) <- value: Get or set the RangedData instance over which applyFun is applied.
applyFun(x), applyFun(x) <- value: Get or set the user function to be applied to each space in the RangedData.
applyParams(x), applyParams(x) <- value: Get or set the list of additional parameters to pass to applyFun.
filterRules (x), filterRules (x) <- value: Get or set the instance of FilterRules that is used to filter each subset of the RangedDat a passed to the user function.
simplify \((x)\), simplify \((x)\) <- value: Get or set a a scalar logical (TRUE or FALSE) indicating whether the list to be returned from rdapply should be simplified as by sapply.
reducerFun (x), reducerFun (x) <- value: Get or set the function that is used to convert the list that would otherwise be returned from rdapply to something more convenient.
reducerParams(x), reducerParams(x) <- value: Get or set a list of additional parameters to pass to reducerFun.

RangedData-class Data on ranges

\section*{Description}

RangedData supports storing data, i.e. a set of variables, on a set of ranges spanning multiple spaces (e.g. chromosomes). Although the data is split across spaces, it can still be treated as one cohesive dataset when desired and extends DataTable. In order to handle large datasets, the data values are stored externally to avoid copying, and the rdapply function facilitates the processing of each space separately (divide and conquer).

\section*{Details}

A RangedData object consists of two primary components: a RangesList holding the ranges over multiple spaces and a parallel SplitDataFrameList, holding the split data. There is also an universe slot for denoting the source (e.g. the genome) of the ranges and/or data.
There are two different modes of interacting with a RangedData. The first mode treats the object as a contiguous "data frame" annotated with range information. The accessors start, end, and width get the corresponding fields in the ranges as atomic integer vectors, undoing the division over the spaces. The [ [ and matrix-style [, extraction and subsetting functions unroll the data in the same way. [ [ <- does the inverse. The number of rows is defined as the total number of ranges and the number of columns is the number of variables in the data. It is often convenient and natural to treat the data this way, at least when the data is small and there is no need to distinguish the ranges by their space.
The other mode is to treat the RangedDat a as a list, with an element (a virtual Ranges/Dat aF rame pair) for each space. The length of the object is defined as the number of spaces and the value returned by the names accessor gives the names of the spaces. The list-style [ subset function behaves analogously. The rdapply function provides a convenient and formal means of applying an operation over the spaces separately. This mode is helpful when ranges from different spaces must be treated separately or when the data is too large to process over all spaces at once.

\section*{Accessor methods}

In the code snippets below, x is a RangedDat a object.
The following accessors treat the data as a contiguous dataset, ignoring the division into spaces:
Array accessors:
nrow ( x ): The number of ranges in x .
\(n \operatorname{col}(x)\) : The number of data variables in \(x\).
\(\operatorname{dim}(x)\) : An integer vector of length two, essentially \(c(n r o w(x), n c o l(x))\).
rownames (x), rownames (x) <- value: Gets or sets the names of the ranges in \(x\).
colnames (x), colnames (x) <- value: Gets the names of the variables in \(x\).
dimnames (x): A list with two elements, essentially list (rownames(x), colnames(x)).
dimnames (x) <- value: Sets the row and column names, where value is a list as described above.
columnMetadata (x): Get the DataFrame of metadata along the value columns, i.e., where each column in \(x\) is represented by a row in the metadata. Note that calling elementMetadata ( \(x\) ) returns the metadata on each space in \(x\).
columnMetadata(x) <- value: Set the DataFrame of metadata for the columns.
within(data, expr, ...): Evaluates expr within data, a RangedData. Any values assigned in expr will be stored as value columns in data, unless they match one of the reserved names: ranges, start, end, width and space. Behavior is undefined if any of the range symbols are modified inconsistently. Modifications to space are ignored.

Range accessors. The type of the return value depends on the type of Ranges. For IRanges, an integer vector. Regardless, the number of elements is always equal to nrow (x).
```

start(x), start(x) <- value: Get or set the starts of the ranges. When setting the
starts, value can be an integer vector of length (sum (elementLengths (ranges (x))))
or an IntegerList object of length length (ranges (x)) and names names (ranges (x)).
end (x), end (x) <- value: Get or set the ends of the ranges. When setting the ends,
value can be an integer vector of length (sum (elementLengths (ranges (x))))
or an IntegerList object of length length (ranges (x)) and names names (ranges (x)).
width(x), width(x) <- value: Get or set the widths of the ranges. When setting
the widths, value can be an integer vector of length (sum (element Lengths (ranges (x))))
or an IntegerList object of length length (ranges(x)) and names names (ranges(x)).

```

These accessors make the object seem like a list along the spaces:
length (x): The number of spaces (e.g. chromosomes) in \(x\).
names (x), names (x) <- value: Get or set the names of the spaces (e.g. "chri"). NULL or a character vector of the same length as \(x\).

Other accessors:
universe(x), universe(x) <- value: Get or set the scalar string identifying the scope of the data in some way (e.g. genome, experimental platform, etc). The universe may be NULL.
ranges (x), ranges(x) <- value: Gets or sets the ranges in \(x\) as a RangesList.
space ( \(x\) ): Gets the spaces from ranges ( \(x\) ).
values (x), values(x) <- value: Gets or sets the data values in \(x\) as a SplitDataFrameList.
score (x), score (x) <- value: Gets or sets the column representing a "score" in \(x\), as a vector. This is the column named score, or, if this does not exist, the first column, if it is numeric. The get method return NULL if no suitable score column is found. The set method takes a numeric vector as its value.

\section*{Constructor}
```

RangedData(ranges = IRanges(), ..., space = NULL, universe = NULL):

```

Creates a RangedData with the ranges in ranges and variables given by the arguments in . . . . See the constructor DataFrame for how the . . . arguments are interpreted.
If ranges is a Ranges object, the space argument is used to split of the data into spaces. If space is NULL, all of the ranges and values are placed into the same space, resulting in a single-space (length one) RangedData object. Otherwise, the ranges and values are split into spaces according to space, which is treated as a factor, like the \(f\) argument in split. If ranges is a RangesList object, then the supplied space argument is ignored and its value is derived from ranges.
If ranges is not a Ranges or RangesList object, this function calls as (ranges, "RangedData") and returns the result if successful.
The universe may be specified as a scalar string by the universe argument.

\section*{Coercion}
as.data.frame(x, row.names=NULL, optional=FALSE, ...): Copy the start, end, width of the ranges and all of the variables as columns in a data.frame. This is a bridge to existing functionality in R , but of course care must be taken if the data is large. Note that optional and . . . are ignored.
as (from, "DataFrame"): Like as.data.frame above, except the result is an DataFrame and it probably involves less copying, especially if there is only a single space.
as (from, "RangedData"): Coerce from to a RangedData, according to the type of from:

Rle, RleList Converts each run to a range and stores the run values in a column named "score".
Ranges, RangesList Creates a RangedData with only the ranges in from; no data columns.
data.frame or DataTable Constructs a RangedData, using the columns "start", "end", and, optionally, "space" columns in from. The other columns become data columns in the result. Any "width" column is ignored.
as.env(x, enclos = parent.frame()): Creates an environment with a symbol for each variable in the frame, as well as a ranges symbol for the ranges. This is efficient, as no copying is performed.

\section*{Subsetting and Replacement}

In the code snippets below, x is a RangedDat a object.
x [i]: Subsets x by indexing into its spaces, so the result is of the same class, with a different set of spaces. i can be numerical, logical, NULL or missing.
\(x[i, j]\) : Subsets \(x\) by indexing into its rows and columns. The result is of the same class, with a different set of rows and columns. The row index \(i\) can either treat \(x\) as a flat table by being a character, integer, or logical vector or treat x as a partitioned table by being a RangesList, LogicalList, or IntegerList of the same length as x .
\(x[\) [i] ]: Extracts a variable from \(x\), where \(i\) can be a character, numeric, or logical scalar that indexes into the columns. The variable is unlisted over the spaces.
For convenience, values of "space" and "ranges" are equivalent to space(x) and unlist (ranges(x)) respectively.
\(\mathrm{x} \$\) name: similar to above, where name is taken literally as a column name in the data.
\(x[[i]]\) <- value: Sets value as column i in \(x\), where i can be a character, numeric, or logical scalar that indexes into the columns. The length of value should equal nrow (x). \(x[\) [i] ] should be identical to value after this operation.
For convenience, \(i=\) "ranges" is equivalent to ranges (x) <- value.
\(x \$\) name <- value: similar to above, where name is taken literally as a column name in the data.

\section*{Splitting and Combining}

In the code snippets below, x is a RangedDat a object.
split (x, f, drop = FALSE) : Split \(x\) according to \(f\), which should be of length equal to nrow (x). Note that drop is ignored here. The result is a RangedDataList where every element has the same length (number of spaces) but different sets of ranges within each space.
rbind (...): Matches the spaces from the RangedData objects in . . . by name and combines them row-wise. In a way, this is the reverse of the split operation described above.
c(x, ..., recursive = FALSE): Combines \(x\) with arguments specified in ..., which must all be RangedData objects. This combination acts as if x is a list of spaces, meaning that the result will contain the spaces of the first concatenated with the spaces of the second, and so on. This function is useful when creating RangedData objects on a space-by-space basis and then needing to combine them.

\section*{Utilities}

In the code snippets below, x is a RangedDat a object.
reduce (x, by, drop.empty.ranges=FALSE, min.gapwidth=1L, with.inframe.attrib \(=F A L S E):\) Merges the ranges in each of the spaces after grouping by the by values columns and returns the result as a RangedData containing the reduced ranges and the by value columns.

\section*{Applying}

There are two ways explicitly supported ways to apply a function over the spaces of a RangedData. The richest interface is rdapply, which is described in its own man page. The simpler interface is an lapply method:
lapply (X, FUN, ....) : Applies FUN to each space in X with extra parameters in . . ..

\section*{Author(s)}

Michael Lawrence

\section*{See Also}

RangedData, DataTable-class, Sequence-class

\section*{Examples}
```

ranges <- IRanges(c(1,2,3),c(4,5,6))
score <- c(10L, 2L, NA)
rd <- RangedData(ranges, score)
range (rd)
rd2 <- RangedData(IRanges(c(5,2,0), c(6,3,1)))
range(rd, rd2)

```
```

RangedDataList-class
Lists of RangedData

```

\section*{Description}

A formal list of RangedDat a objects. Extends and inherits all its methods from Sequence. One use case is to group together all of the samples from an experiment generating data on ranges.

\section*{Constructor}

RangedDataList (...): Concatenates the RangedData objects in . . . into a new RangedDataList.

\section*{Combining and Splitting}
stack(x, indName = "sample"): Uses rbind to combine the elements into a single RangedData object, with a factor, named indName, in the values indicating the source of each feature.

\section*{Author(s)}

Michael Lawrence

\section*{See Also}

RangedData, the element type of this Sequence.

\section*{Examples}
ranges \(<-\operatorname{IRanges}(c(1,2,3), c(4,5,6))\)
a <- RangedData(IRanges \((c(1,2,3), c(4,5,6))\), \(\operatorname{score}=c(10 L, 2 L, N A))\)
\(\mathrm{b}<-\operatorname{RangedData}(\operatorname{IRanges}(\mathrm{c}(1,2,4), \mathrm{c}(4,7,5))\), score \(=\mathrm{c}(3 \mathrm{~L}, 5 \mathrm{~L}, 7 \mathrm{~L}))\)
RangedDataList (sample1 = a, sample2 = b)

\section*{RangedSelection-class}

Selection of ranges and columns

\section*{Description}

A RangedSelection represents a query against a table of interval data in terms of ranges and column names. The ranges select any table row with an overlapping interval. Note that the intervals are always returned, even if no columns are selected.

\section*{Details}

Traditionally, tabular data structures have supported the subset function, which allows one to select a subset of the rows and columns from the table. In that case, the rows and columns are specified by two separate arguments. As querying interval data sources, especially those external to \(R\), such as binary indexed files and databases, is increasingly common, there is a need to encapsulate the row and column specifications into a single data structure, mostly for the sake of interface cleanliness. The RangedSelection class fills that role.

\section*{Constructor}

RangedSelection(ranges \(=\) RangesList(), colnames = character()):Constructors a RangedSelection with the given ranges and colnames.

\section*{Coercion}
as (from, "RangedSelection"): Coerces from to a RangedSelection object. Typically, from is a RangesList, the ranges of which become the ranges in the new RangedSelection.

\section*{Accessors}

In the code snippets below, x is always a RangedSelection.
ranges(x), ranges(x) <- value: Gets or sets the ranges, a RangesList, that select rows with overlapping intervals.
colnames(x), colnames(x) <- value: Gets the names, a character vector, indicating the columns.

\section*{Author(s)}

Michael Lawrence

\section*{Examples}
```

rl <- RangesList(chr1 = IRanges(c(1, 5), c(3, 6)))
RangedSelection(rl)
as(rl, "RangedSelection") \# same as above
RangedSelection(rl, "score")

```

Ranges-class Ranges objects

\section*{Description}

The Ranges virtual class is a general container for storing a set of integer ranges.

\section*{Details}

A Ranges object is a vector-like object where each element describes a "range of integer values".
A "range of integer values" is a finite set of consecutive integer values. Each range can be fully described with exactly 2 integer values which can be arbitrarily picked up among the 3 following values: its "start" i.e. its smallest (or first, or leftmost) value; its "end" i.e. its greatest (or last, or rightmost) value; and its "width" i.e. the number of integer values in the range. For example the set of integer values that are greater than or equal to -20 and less than or equal to 400 is the range that starts at -20 and has a width of 421 . In other words, a range is a closed, one-dimensional interval with integer end points and on the domain of integers.
The starting point (or "start") of a range can be any integer (see start below) but its "width" must be a non-negative integer (see width below). The ending point (or "end") of a range is equal to its "start" plus its "width" minus one (see end below). An "empty" range is a range that contains no value i.e. a range that has a null width. Depending on the context, it can be interpreted either as just the empty set of integers or, more precisely, as the position between its "end" and its "start" (note that for an empty range, the "end" equals the "start" minus one).

The length of a Ranges object is the number of ranges in it, not the number of integer values in its ranges.
A Ranges object is considered empty iff all its ranges are empty.
Ranges objects have a vector-like semantic i.e. they only support single subscript subsetting (unlike, for example, standard R data frames which can be subsetted by row and by column).

The Ranges class itself is a virtual class. The following classes derive directly from the Ranges class: IRanges and IntervalTree.

\section*{Methods}

In the code snippets below, \(x, y\) and object are Ranges objects. Not all the functions described below will necessarily work with all kinds of Ranges objects but they should work at least for IRanges objects. Also more operations on Ranges objects are described in the man page for Rangesutils (shift, restrict, narrow, reduce, etc...), for IntervalTree objects (findOverlaps), and for RangesList objects (split method for Ranges objects).
length (x): The number of ranges in \(x\).
start ( \(x\) ): The start values of the ranges. This is an integer vector of the same length as \(x\).
width(x): The number of integer values in each range. This is a vector of non-negative integers of the same length as \(x\).
end (x): start(x) + width(x) - 1L
\(\operatorname{mid}(x):\) returns the midpoint of the range, \(\operatorname{start}(x)+\) floor \(((\) width \((x)-1) / 2)\).
names \((x)\) : NULL or a character vector of the same length as \(x\).
update (object, ...) : Convenience method for combining multiple modifications of object in one single call. For example object <- update(object, start=start(object)2L, end=end (object) +2L) is equivalent to start (object) <- start(object) 2L; end(object) <- end(object) \(+2 L\).
isEmpty \((\mathrm{x})\) : Return a logical value indicating whether x is empty or not.
isDisjoint (x): Return a logical value indicating whether the ranges \(x\) are disjoint (i.e. nonoverlapping).
as.matrix(x, ....): Convert \(x\) into a 2-column integer matrix containing start (x) and width (x). Extra arguments (. . .) are ignored.
as.data.frame(x, row.names=NULL, optional=FALSE, ...): Convert x into a standard R data frame object. row. names must be NULL or a character vector giving the row names for the data frame, and optional and any additional argument (. . .) is ignored. See ?as.data.frame for more information about these arguments.
as.integer ( \(x\) ): Convert \(x\) into an integer vector, by converting each range into the integer sequence formed by from: to and concatenating them together.
unlist(x, recursive = TRUE, use.names \(=\) TRUE):Similartoas.integer(x) except can add names to elements.
x[[i]]: Return integer vector start(x[i]):end(x[i]) denoted by i. Subscript i can be a single integer or a character string.
\(x[i]\) : Return a new Ranges object (of the same type as \(x\) ) made of the selected ranges. i can be a numeric vector, a logical vector, NULL or missing. If x is a NormalIRanges object and i a positive numeric subscript (i.e. a numeric vector of positive values), then i must be strictly increasing.
rep (x, times, length. out, each): Repeats the values in \(x\) through one of the following conventions:
times Vector giving the number of times to repeat each element if of length length (x), or to repeat the Ranges elements if of length 1.
length. out Non-negative integer. The desired length of the output vector.
each Non-negative integer. Each element of x is repeated each times.
c ( \(\mathrm{x}, \mathrm{F} . \mathrm{e}\) ): Combine x and the Ranges objects in . . . together. Any object in . . . must belong to the same class as \(x\), or to one of its subclasses, or must be NULL. The result is an object of the same class as \(x\). NOTE: Only works for IRanges (and derived) objects for now.
\(x * y\) : The arithmetic operation \(x * y\) is for centered zooming. It symmetrically scales the width of \(x\) by \(1 / y\), where \(y\) is a numeric vector that is recycled as necessary. For example, \(x\) * 2 results in ranges with half their previous width but with approximately the same midpoint. The ranges have been "zoomed in". If \(y\) is negative, it is equivalent to \(x *(1 / a b s(y))\). Thus, \(x\) * -2 would double the widths in \(x\). In other words, \(x\) has been "zoomed out".
\(x+y\) : Expands the ranges in \(x\) on either side by the corresponding value in the numeric vector \(y\).

\section*{Normality}

A Ranges object x is implicitly representing an arbitrary finite set of integers (that are not necessarily consecutive). This set is the set obtained by taking the union of all the values in all the ranges in x . This representation is clearly not unique: many different Ranges objects can be used to represent the same set of integers. However one and only one of them is guaranteed to be "normal".
By definition a Ranges object is said to be "normal" when its ranges are: (a) not empty (i.e. they have a non-null width); (b) not overlapping; (c) ordered from left to right; (d) not even adjacent (i.e. there must be a non empty gap between 2 consecutive ranges).
Here is a simple algorithm to determine whether \(x\) is "normal": (1) if length \((x)==0\), then \(x\) is normal; (2) if length ( \(x\) ) \(==1\), then \(x\) is normal iff width \((x) \quad>=1\); (3) if length ( \(x\) ) \(>=2\), then \(x\) is normal iff:
```

start(x)[i] <= end(x)[i] < start(x)[i+1] <= end(x)[i+1]

```
for every \(1<=\) i < length ( x ).
The obvious advantage of using a "normal" Ranges object to represent a given finite set of integers is that it is the smallest in terms of of number of ranges and therefore in terms of storage space. Also the fact that we impose its ranges to be ordered from left to right makes it unique for this representation.
A special container (NormalIRanges) is provided for holding a "normal" IRanges object: a NormalIRanges object is just an IRanges object that is guaranteed to be "normal".

Here are some methods related to the notion of "normal" Ranges:
isNormal (x): Return a logical value indicating whether x is "normal" or not.
whichFirstNotNormal (x) : Return NA if \(x\) is normal, or the smallest valid indice i in \(x\) for which \(x[1: i]\) is not "normal".

Must be FALSE.
fromLast TRUE or FALSE.
... Ranges objects for order.
na.last Ignored.
decreasing TRUE or FALSE.
ties.method A character string specifying how ties are treated. Only "first" is supported
for now.

```

\section*{Details}

Two ranges are considered equal iff they share the same start and width. Note that with this definition, 2 empty ranges are generally not equal (they need to share the same start to be considered equal). This means that, when it comes to comparing ranges, an empty range is interpreted as a position between its end and start. For example, a typical usecase is comparison of insertion points defined along a string (like a DNA sequence) and represented as empty ranges.
Ranges are ordered by starting position first, and then by width. This way, the space of ranges is totally ordered. The order, sort and rank methods for Ranges objects are consistent with this order.
duplicated \((x)\) : Determines which elements of \(x\) are equal to elements with smaller subscripts, and returns a logical vector indicating which elements are duplicates. It is semantically equivalent to duplicated (as.data.frame (x)). See duplicated in the base package for more details.
unique (x): Removes duplicate ranges from \(x\). See unique in the base package for more details.
order (. . .) : Returns a permutation which rearranges its first argument (a Ranges object) into ascending order, breaking ties by further arguments (also Ranges objects). See order in the base package for more details.
sort (x): Sorts \(x\). See sort in the base package for more details.
rank(x, na.last=TRUE, ties.method=c("average", "first", "random", "max", "min")): Returns the sample ranks of the ranges in \(x\). See rank in the base package for more details.

Ranges-utils Ranges utility functions

\section*{Description}

Utility functions for modifying Ranges objects.

\section*{Usage}
```

flank(x, width, start=TRUE, both=FALSE, use.names=TRUE)
narrow(x, start=NA, end=NA, width=NA, use.names=TRUE)
reflect(x, bounds, use.names=TRUE)
resize(x, width, fix="start", use.names=TRUE, ...)
restrict(x, start=NA, end=NA, keep.all.ranges=FALSE, use.names=TRUE)
shift(x, shift, use.names=TRUE)

## S4 method for signature 'Ranges':

range(x, ..., na.rm = FALSE)

## S4 method for signature 'Ranges':

reduce(x, drop.empty.ranges=FALSE, min.gapwidth=1L,
with.inframe.attrib=FALSE)
threebands(x, start=NA, end=NA, width=NA)

```

\section*{Arguments}
x
width

An Ranges object.
For narrow and threebands, a vector of integers, eventually with NAs. See the SEW (Start/End/Width) interface for the details (?solveUserSEW).
For resize and flank, the width of the resized or flanking regions. Note that if both is TRUE, this is effectively doubled. Recycled as necessary so that each element corresponds to a range in x .
```

start, end A single integer or NA for all functions except narrow, threebands, and
flank.
For narrow and threebands, the supplied start and end arguments must
be vectors of integers, eventually with NAs, that contain coordinates relative to
the current ranges. See the Details section below.
For flank, start is a logical indicating whether x should be flanked at the
start (TRUE) or the end (FALSE). Recycled as necessary so that each element corresponds to a range in x .
both If TRUE, extends the flanking region width positions into the range. The resulting range thus straddles the end point, with width positions on either side.

```
```

use.names TRUE or FALSE. Should names be preserved?

```
use.names TRUE or FALSE. Should names be preserved?
bounds An IRanges object to serve as the reference bounds for the reflection, see below.
fix For resize, a character vector or character Rle of length 1 or length(x)
    containing the values "start", "end", and "center" denoting what to use
    as an anchor for each element in }x\mathrm{ .
keep.all.ranges
    TRUE or FALSE. Should ranges that don't overlap with the interval specified by
    start and end be kept? Note that "don't overlap" means that they end strictly
    before start - 1 or start strictly after end + 1. Ranges that end at start
    - 1 or start at end + 1 are always kept and their width is set to zero in the
    returned IRanges object.
shift A single integer.
drop.empty.ranges
    TRUE or FALSE. Should empty ranges be dropped?
min.gapwidth Ranges separated by a gap of at least min.gapwidth positions won't be
merged in the Ranges object returned by reduce. Otherwise, they will.
with.inframe.attrib
    TRUE or FALSE. For internal use.
    ... For range, additional Ranges to consider.
na.rm Ignored
```

## Details

flank generates flanking ranges for each range in $x$. If start is TRUE for a given range, the flanking occurs at the start, otherwise the end. The widths of the flanks are given by the width parameter. The widths can be negative, in which case the flanking region is reversed so that it represents a prefix or suffix of the range in $x$. The flank operation is illustrated below for a call of the form flank ( $\mathrm{x}, 3$, TRUE), where x indicates a range in x and - indicates the resulting flanking region:
$---x \times x \times x \times x$

If start were FALSE:

XXXXXXX---

For negative width, i.e. flank ( $\mathrm{x},-3$, FALSE), where $*$ indicates the overlap between x and the result:

## XXXX***

If both is TRUE, then, for all ranges in x , the flanking regions are extended into (or out of, if width is negative) the range, so that the result straddles the given endpoint and has twice the width given by width. This is illustrated below for flank (x, 3, both=TRUE):
narrow narrows the ranges in x i.e. each range in the returned Ranges object is a subrange of the corresponding range in x . The supplied start/end/width values are solved by a call to solveUserSEW (width(x), start=start, end=end, width=width) and therefore must be compliant with the rules of the SEW (Start/End/Width) interface (see ?solveUserSEW for the details). Then each subrange is derived from the original range according to the solved start/end/width values for this range. Note that those solved values are interpreted relatively to the original range.
reflect "reflects" or reverses each range in $x$ relative to the corresponding range in bounds, which is recycled as necessary. Reflection preserves the width of a range, but shifts it such the distance from the left bound to the start of the range becomes the distance from the end of the range to the right bound. This is illustrated below, where x represents a range in x and [ and ] indicate the bounds:

```
[..XXX.....]
becomes
[.....xxx..]
```

resize resizes the ranges to the specified width where either the start, end, or center is used as an anchor.
restrict restricts the ranges in x to the interval specified by the start and end arguments.
shift shifts all the ranges in x .
range returns an IRanges instance with a single range, from the minimum start to the maximum end in the combined ranges of $x$ and the arguments in . . .
reduce first orders the ranges in x from left to right, then merges the overlapping or adjacent ones.
threebands extends the capability of narrow by returning the 3 ranges objects associated to the narrowing operation. The returned value $y$ is a list of 3 ranges objects named "left", "middle" and "right". The middle component is obtained by calling narrow with the same arguments (except that names are dropped). The left and right components are also instances of the same class as $x$ and they contain what has been removed on the left and right sides (respectively) of the original ranges during the narrowing.
Note that original object $x$ can be reconstructed from the left and right bands with punion (y\$left, y\$right, fill.gap=TRUE).

## Examples

```
vec <- as.integer(c(19, 5, 0, 8, 5))
x <- successiveIRanges(vec)
x
shift(x, -3)
restrict(x, start=12, end=34)
restrict(x, start=20)
restrict(x, start=21)
restrict(x, start=21, keep.all.ranges=TRUE)
y <- x[width(x) != 0]
narrow(y, start=4, end=-2)
narrow(y, start=-4, end=-2)
narrow(y, end=5, width=3)
narrow(y, start =c(3, 4, 2, 3), end =c(12, 5, 7, 4))
resize(y, width = 200)
resize(y, width = 2, fix = "end")
z <- threebands(y, start=4, end=-2)
y0 <- punion(z$left, z$right, fill.gap=TRUE)
identical(y, y0) # TRUE
threebands(y, start=-5)
x <- IRanges(start=c(-2, 6, 9, -4, 1, 0, -6, 3, 10),
    width=c( 5, 0, 6, 1, 4, 3, 2, 0, 3))
reduce(x)
reduce(x, drop.empty.ranges=TRUE)
ir1 <- IRanges(c(2,5,1), c(3,7,3))
bounds <- IRanges(c(0, 5, 3), c(10, 6, 9))
reflect(ir1, bounds)
flank(ir1, 2)
flank(ir1, 2, FALSE)
flank(ir1, 2, c(FALSE, TRUE, FALSE))
flank(ir1, c(2, -2, 2))
flank(ir1, 2, both = TRUE)
flank(ir1, 2, FALSE, TRUE)
flank(ir1, -2, FALSE, TRUE)
```

## Description

An extension of Sequence that holds only Ranges objects. Useful for storing ranges over a set of spaces (e.g. chromosomes), each of which requires a separate Ranges object. As a Sequence, RangesList may be annotated with its universe identifier (e.g. a genome) in which all of its spaces exist.

## Accessors

In the code snippets below, x is a RangesList object.
All of these accessors collapse over the spaces:
start(x), start(x) <- value: Get or set the starts of the ranges. When setting the starts, value can be an integer vector of length (sum (elementLengths(x))) or an IntegerList object of length length(x) and names names (x).
end (x), end (x) <- value: Get or set the ends of the ranges. When setting the starts, value can be an integer vector of length (sum(elementLengths(x))) or an IntegerList object of length length (x) and names names (x).
width(x), width(x) <- value: Get or set the widths of the ranges. When setting the starts, value can be an integer vector of length (sum (elementLengths (x))) or an IntegerList object of length length ( x ) and names names ( x ).
space (x): Gets the spaces of the ranges as a character vector. This is equivalent to names (x), except each name is repeated according to the length of its element.

These accessors are for the universe identifier:
universe (x) : gets the name of the universe as a single string, if one has been specified, NULL otherwise.
universe (x) <- value: sets the name of the universe to value, a single string or NULL.

## Constructor

RangesList(..., universe = NULL): Each Ranges in ... becomes an element in the new RangesList, in the same order. This is analogous to the list constructor, except every argument in . . . must be derived from Ranges. The universe is specified by the universe parameter, which should be a single string or NULL, to leave unspecified.

## Subsetting

In the code snippets below, x is a RangesList object.

```
x[i]: Subset x by index i, with the same semantics as a basic Sequence, except i may itself
``` be a RangesList, in which case only the ranges in \(x\) that overlap with those in \(i\) are kept. See the findOverlaps method for more details.

\section*{Coercion}

In the code snippets below, x and from are a RangesList object.
as.data.frame(x, row.names = NULL, optional = FALSE):Coercesxtoadata.frame. Essentially the same as calling data.frame (space=rep (names (x), elementLengths (x)), as.data.frame (unlist ( \(x\), use. names=FALSE))).
as (from, "RangedData"): Coerces from to a RangedData with zero columns and the same ranges as in from.
as(from, "SimpleIRangesList"): Coerces from, to a SimpleIRangesList, requiring that all Ranges elements are coerced to internal IRanges elements. This is a convenient way to ensure that all Ranges have been imported into R (and that there is no unwanted overhead when accessing them).
as (from, "CompressedIRangesList"): Coerces from, to CompressedIRangesList, requiring that all Ranges elements are coerced to internal IRanges elements. This is a convenient way to ensure that all Ranges have been imported into R (and that there is no unwanted overhead when accessing them).
as (from, "SimpleNormalIRangesList"): Coerces from, to a SimpleNormalIRangesList, requiring that all Ranges elements are coerced to internal NormalIRanges elements.
as (from, "CompressedNormalIRangesList"): Coerces from, to a CompressedNormalIRangesLis requiring that all Ranges elements are coerced to internal NormalIRanges elements.

\section*{Arithmetic Operations}

Any arithmetic operation, such as \(x+y, x * y\), etc, where \(x\) is a RangesList, is performed identically on each element. Currently, Ranges supports only the * operator, which zooms the ranges by a numeric factor.

## S4 method for signature 'RangesList,RangesList':

intersect(x, y)

## S4 method for signature 'RangesList,RangesList':

setdiff(x, y)

```

\section*{Arguments}
\begin{tabular}{ll}
\(\mathrm{x}, \mathrm{y}\) \\
start, end \(\quad\) & \begin{tabular}{l} 
A RangesList \\
For flank, start must be either a logical vector or a LogicalList object in- \\
dicating whether x should be flanked at the start (TRUE) or the end (FALSE).
\end{tabular} \\
\begin{tabular}{l} 
Recycled as necessary so that each element corresponds to a range in x.
\end{tabular} \\
\begin{tabular}{l} 
For narrow, start and end must be either an integer vector or a IntegerList \\
object containing coordinates relative to the current ranges.
\end{tabular}
\end{tabular}

For restrict, start and end must be either a single integer or NA.
For gaps, start and end must be an integer vector containing the coordinate bounds for each RangesList element.
width For flank and resize, either an integer vector or an IntegerList object containing the width of the flanking or resized regions. Recycled as necessary so that each element corresponds to a range in \(x\). (Note for flank: if both is TRUE, this is effectively doubled.)
For narrow, either an integer vector or a IntegerList object containing the widths to narrow to. See the SEW (Start/End/Width) interface for the details (?solveUserSEW).
both If TRUE, extends the flanking region width positions into the range. The resulting range thus straddles the end point, with width positions on either side.
use.names TRUE or FALSE. Should names be preserved?
fix For resize, a character vector of length 1, a CharacterList object, or a 'character' RleList object containing the values "start", "end", and "center" denoting what to use as an anchor for each element in x .
keep.all.ranges
TRUE or FALSE. Should ranges that don't overlap with the interval specified by start and end be kept? Note that "don't overlap" means that they end strictly before start - 1 or start strictly after end +1 . Ranges that end at start - 1 or start at end +1 are always kept and their width is set to zero in the returned RangesList object.
shift Either an integer vector or a IntegerList object containing the shift information. Recycled as necessary so that each element corresponds to a range in x .
drop.empty.ranges
TRUE or FALSE. Should empty ranges be dropped?
min.gapwidth Ranges separated by a gap of at least min.gapwidth positions won't be merged in the Ranges object returned by reduce. Otherwise, they will.
with.inframe.attrib
TRUE or FALSE. For internal use.
... For range, additional RangesList to consider.
na.rm Ignored

\section*{Details}

The flank method generates flanking ranges for each range in x .
The narrow method narrows the ranges in x i.e. each range in the returned RangesList object is a subrange of the corresponding range in \(x\).
The resize method resizes the ranges to the specified width where either the start or end is used as an anchor.

The restrict method restricts the ranges in \(x\) to the interval specified by the start and end arguments.

The shift method shifts all the ranges in x .
The disjoin method returns disjoint ranges by finding the within element union of the end points of \(x\).

The gaps method takes the complement (via gaps) of each element in the list and returns the result as a RangesList.
range finds the range, i.e. a Ranges with one range, from the minimum start to the maximum end, on each element in \(x\) and returns the result as a RangesList. If there are additional RangesList objects in . . ., they are merged into \(x\) by name, if all objects have names, otherwise, if they are all of the same length, by position. Else, an exception is thrown.
The reduce method merges (via reduce) each of the elements in the list and returns the result as a RangesList.

The union method performs elementwise union operations for two RangesList objects.
The intersect method performs elementwise intersect operations for two RangesList objects.
The setdiff method performs elementwise setdiff operations for two RangesList objects.

\section*{Value}

A RangesList object. For flank, narrow, resize, restrict, and shift, the length is the same as that of \(x\).

```
RangesMatching-class

\section*{Description}

The RangesMat ching class stores a set of matchings between the ranges in one Ranges object and the ranges in another. Currently, RangesMatching are used to represent the result of a call to findOverlaps, though other matching operations are imaginable.

\section*{Details}

The as.matrix method coerces a RangesMatching to a two column matrix with one row for each matching, where the value in the first column is the index of a range in the first (query) Ranges and the index of the matched subject range is in the second column. The matchMatrix function returns the same thing, but use of as.matrix is preferred.

The as.table method counts the number of matchings for each query range and outputs the counts as a table.

To transpose a RangesMatching \(x\), so that the subject and query are interchanged, call \(t(x)\). This allows, for example, counting the number of subjects that matched using as.table.

To get the actual regions of intersection between the overlapping ranges, use the ranges accessor.

\section*{Coercion}

In the code snippets below, x is a RangesMat ching object.
as.matrix (x): Coerces \(x\) to a two column integer matrix, with each row representing a matching between a query index (first column) and subject index (second column).
as.table \((x)\) : counts the number of matchings for each query range in \(x\) and outputs the counts as atable.
\(t(x)\) : Interchange the query and subject in \(x\), returns a transposed RangesMatching.

\section*{Accessors}
queryHits (x): Gets the indices of overlapping ranges in the query, equivalent to as.matrix \((x)[, 1]\).
subjectHits (x): Gets the indices of overlapping ranges in the subject, equivalent to as.matrix (x) [, 2].
matchMatrix(x): A synonym for as.matrix, above.
ranges ( \(x\), query, subject): returns a Ranges holding the intersection of the ranges in the Ranges objects query and sub ject, which should be the same subject and query used to generate x . Eventually, we might store the query and subject inside x , in which case the arguments would be redundant.
length \((x)\) : get the number of matches
nrow ( \(x\) ): get the number of queries in the matching
\(n \operatorname{col}(x)\) : get the number of subjects in the matching
dim (x) : get a two-element integer vector, essentially \(c(n r o w(x), n c o l(x))\).

\section*{Author(s)}

Michael Lawrence

\section*{See Also}
findOverlaps, which generates an instance of this class.

\section*{Examples}
```

    query <- IRanges(c(1, 4, 9), c(5, 7, 10))
    subject <- IRanges(c(2, 2, 10), c(2, 3, 12))
    tree <- IntervalTree(subject)
    matchings <- findOverlaps(query, tree)
    as.matrix(matchings)
    as.table(matchings) # hits per query
    as.table(t(matchings)) # hits per subject
    ```
RangesMatchingList-class

List of Matchings between Ranges

\section*{Description}

The RangesMatchingList class stores a set of matchings, represented as RangesMatching objects, between the ranges in one RangesList object and the ranges in another.

\section*{Details}

Roughly the same set of utilities are provided for RangesMat chingList as for RangesMat ching:
The as.matrix method coerces a RangesMatchingList in a similar way to RangesMatching, except a column is prepended that indicates which space (or element in the query RangesList) to which the row corresponds.
The as.table method flattens or unlists the list, counts the number of matchings for each query range and outputs the counts as a table, which has the same shape as from a single RangesMathing.

To transpose a RangesMatchingList \(x\), so that the subject and query in each space are interchanged, call \(t(x)\). This allows, for example, counting the number of subjects that matched using as.table.

To get the actual regions of intersection between the overlapping ranges, use the ranges accessor.

\section*{Coercion}

In the code snippets below, x is a RangesMatchingList object.
as.matrix(x): calls as.matrix on each RangesMatching, combines them row-wise and offsets the indices so that they are aligned with the result of calling unlist on the query and subject.
as.table(x): counts the number of matchings for each query range in \(x\) and outputs the counts as a table, which is aligned with the result of calling unlist on the query.
\(t(x)\) : Interchange the query and subject in each space of \(x\), returns a transposed RangesMat chingList.

\section*{Accessors}
queryHits (x): Gets the indices of overlapping ranges in the query, equivalent to as.matrix(x)[,1].
subjectHits (x): Gets the indices of overlapping ranges in the subject, equivalent to as.matrix (x) [, 2] .
space(x): gets the character vector naming the space in the query RangesList for each match, or NULL if the query did not have any names.
ranges(x, query, subject): returns a RangesList holding the intersection of the ranges in the RangesList objects query and subject, which should be the same subject and query used to generate x . Eventually, we might store the query and subject inside x , in which case the arguments would be redundant.

\section*{Note}

This class is highly experimental. It has not been well tested and may disappear at any time.

\section*{Author(s)}

Michael Lawrence

\section*{See Also}
findOverlaps, which generates an instance of this class.

\section*{Rle-class Rle objects}

\section*{Description}

The Rle class is a general container for storing an atomic vector that is stored in a run-length encoding format. It is based on the rle function from the base package.

\section*{Constructors}

Rle (values) : This constructor creates an Rle instances out of an atomic vector values.
Rle (values, lengths): This constructor creates an Rle instances out of an atomic vector or factor object values and an integer or numeric vector lengths with all positive elements that represent how many times each value is repeated. The length of these two vectors must be the same.
as (from, "Rle"): This constructor creates an Rle instances out of an atomic vector from.

\section*{Accessors}

In the code snippets below, x is an Rle object:
runLength (x): Returns the run lengths for \(x\).
runValue (x) : Returns the run values for \(x\).
nrun ( \(x\) ): Returns the number of runs in \(x\).
start (x): Returns the starts of the runs for x .
end \((x)\) : Returns the ends of the runs for \(x\).
width(x): Same as runLength(x).

\section*{Replacers}

In the code snippets below, x is an Rle object:
runLength (x) <- value: Replaces \(x\) with a new Rle object using run values runValue (x) and run lengths value.
runValue (x) <- value: Replaces \(x\) with a new Rle object using run values value and run lengths runLength(x).

\section*{Coercion}

In the code snippets below, x and from are Rle objects:
as.vector(x), as (from, "vector"): Creates an atomic vector of the most appropriate type based on the values contained in \(x\).
as.logical(x), as(from, "logical"): Creates a logical vector based on the values contained in x .
as.integer(x), as (from, "integer"): Creates an integer vector based on the values contained in x .
as.numeric(x), as(from, "numeric"): Creates a numeric vector based on the values contained in x .
as.complex(x), as (from, "complex"): Creates a complex vector based on the values contained in x .
as.character(x), as (from, "character"): Creates a character vector based on the values contained in x .
as.raw (x), as (from, "raw"): Creates a raw vector based on the values contained in \(x\).
as.factor (x), as (from, "factor"): Creates a factor object based on the values contained in x .
as.data.frame(x), as (from, "data.frame"): Creates a data.frame with a single column holding the result of as.vector ( x ).
as (from, "IRanges"): Creates an IRanges instance from a logical Rle. Note that this instance is guaranteed to be normal.
as (from, "NormalIRanges"): Creates a NormalIRanges instance from a logical Rle.

\section*{Group Generics}

Rle objects have support for S 4 group generic functionality:
```

Arith "+", " - ", "*", "^", "%%", "%/%", " / "
Compare "==", ">", "<", "!=", "<=", ">="
Logic "\&","|"
Ops "Arith", "Compare", "Logic"
Math "abs","sign", "sqrt", "ceiling", "floor", "trunc", "cummax", "cummin",
"cumprod", "cumsum", "log", "log10", "log2", "log1p", "acos", "acosh",
"asin", "asinh", "atan", "atanh", "exp", "expm1", "cos", "cosh", "sin",
"sinh", "tan", "tanh", "gamma", "lgamma", "digamma", "trigamma"
Math2 "round", "signif"
Summary "max", "min", "range", "prod", "sum", "any", "all"
Complex "Arg", "Conj", "Im", "Mod", "Re"

```

See S4groupGeneric for more details.

\section*{General Methods}

In the code snippets below, x is an Rle object:
```

x[i, drop = !is.null(getOption("dropRle")) \&\& getOption("dropRle")]:

```

Subsets \(x\) by index \(i\), where \(i\) can be positive integers, negative integers, a logical vector of the same length as x , an Rle object of the same length as x containing logical values, or an IRanges object. When drop \(=\) FALSE returns an Rle object. When drop \(=\) TRUE, returns an atomic vector.
```

x[i] <- value: Equivalent to seqselect(x, i) <- value.

```
\(x \% i n \%\) table: Returns a logical Rle representing set membership in table.
aggregate(x, by, FUN, start = NULL, end = NULL, width = NULL, frequency
    = NULL, delta = NULL, ..., simplify = TRUE)): Generates summaries on
    the specified windows and returns the result in a convenient form:
    by An object with start, end, and width methods.
    FUN The function, found via match. fun, to be applied to each window of x .
    start, end, width the start, end, or width of the window. If by is missing, then must
        supply two of the three.
    frequency, delta Optional arguments that specify the sampling frequency and increment
        within the window.
    ... Further arguments for FUN.
    simplify A logical value specifying whether or not the result should be simplified to a
        vector or matrix if possible.
append (x, values, after = length(x)): Insert one Rle into another Rle.
    values the Rle to insert.
    after the subscript in \(x\) after which the values are to be inserted.
\(c(x, \ldots)\) : Combines a set of Rle objects.
findRange ( x , vec) : Returns an IRanges object representing the ranges in Rle vec that are referenced by the indices in the integer vector \(x\).
findRun (x, vec): Returns an integer vector indicating the run indices in Rle vec that are referenced by the indices in the integer vector \(x\).
head \((x, n=6 L)\) : If \(n\) is non-negative, returns the first \(n\) elements of \(x\). If \(n\) is negative, returns all but the last abs ( \(n\) ) elements of \(x\).
is.na(x): Returns a logical Rle indicating with values are NA.
is.unsorted(x, na.rm = FALSE, strictly = FALSE): Returns a logical value specifying if \(x\) is unsorted.
na.rm remove missing values from check.
strictly check for _strictly_increasing values.
length (x): Returns the underlying vector length of x .
match(x, table, nomatch = NA_integer_, incomparables = NULL):Matches
the values in \(x\) to table:
table the values to be matched against.
nomatch the value to be returned in the case when no match is found.
incomparables a vector of values that cannot be matched. Any value in x matching a value in this vector is assigned the nomatch value.
rep(x, times, length.out, each), rep.int(x, times): Repeats the values in \(x\) through one of the following conventions:
times Vector giving the number of times to repeat each element if of length length ( x ) , or to repeat the whole vector if of length 1.
length. out Non-negative integer. The desired length of the output vector.
each Non-negative integer. Each element of \(x\) is repeated each times.
rev (x): Reverses the order of the values in \(x\).
seqselect (x, start \(=\) NULL, end \(=\) NULL, width \(=\) NULL): Creates a new Rle object using consecutive subsequences from x specified by two of the three following values: start, end, and width. See seqselect for more details.
seqselect (x, start=NULL, end=NULL, width=NULL) <- value: Similar to window<-
, except that multiple consecutive subsequences can be replaced by a constant value. As
such two of the three start, end, and width arguments can be used to specify the consecutive subsequences. Alternatively, start can take a Ranges object or something that can be converted to a Ranges object like an integer vector, logical vector or logical Rle.
shiftApply (SHIFT, X, Y, FUN, ..., OFFSET = OL, simplify = TRUE, verbose
\(=\) FALSE): Let \(i\) be the indices in SHIFT, X_i = window (X, 1 + OFFSET, length (X)
- SHIFT[i]), andY_i = window(Y, 1 + SHIFT[i], length(Y) - OFFSET).

Calculates the set of FUN (X_i, Y_i, ...) values and return the results in a convenient
form:
SHIFT A non-negative integer vector of shift values.
X, Y The Rle objects to shift.
FUN The function, found via match. fun, to be applied to each set of shifted vectors.
... Further arguments for FUN.
OFFSET A non-negative integer offset to maintain throughout the shift operations.
simplify A logical value specifying whether or not the result should be simplified to a vector or matrix if possible.
verbose A logical value specifying whether or not to print the \(i\) indices to track the iterations.
show (object) : Prints out the Rle object in a user-friendly way.
sort ( x , decreasing = FALSE, na.last \(=\) NA): Sorts the values in x .
decreasing If TRUE, sort values in decreasing order. If FALSE, sort values in increasing order.
na. last If TRUE, missing values are placed last. If FALSE, they are placed first. If NA, they are removed.
split(x, f, drop = FALSE): Splits xaccording to f to create a CompressedRleList object. Empty list elements are removed if drop is TRUE.
splitRanges (x): Returns a CompressedIRangesList object that contain the ranges for each of the unique run values.
subset (x, subset): Returns a new Rle object made of the subset using logical vector subset.
summary(object, ..., digits = max(3, getOption("digits") - 3)):Summarizes the Rle object using an atomic vector convention. The digits argument is used for number formatting with signif().
table (...) : Returns a table containing the counts of the unique values.
tail ( \(\mathrm{x}, \mathrm{n}=6 \mathrm{~L}\) ): If n is non-negative, returns the last n elements of x . If n is negative, returns all but the first abs ( \(n\) ) elements of \(x\).
unique (x, incomparables = FALSE, ...) : Returns the unique run values. The incomparables argument takes a vector of values that cannot be compared with FALSE being a special value that means that all values can be compared.
window (x, start \(=N A\), end \(=\) NA, width \(=\) NA, frequency \(=\) NULL, delta
\(=\) NULL, . . .) : Extract the subsequence window from x specified by:
start, end, width The start, end, or width of the window. Two of the three are required.
frequency, delta Optional arguments that specify the sampling frequency and increment within the window.
window (x, start \(=\) NA, end \(=\) NA, width \(=\) NA, keepLength \(=\) TRUE) <- value:
Replace the subsequence window specified on the left (i.e. the subsequence in x specified by start, end and width) by value. value must either be of class Rle, belong to a subclass of Rle, be coercible to Rle, or be NULL. If keepLength is TRUE, the elements of value are repeated to create an Rle with the same number of elements as the width of the subsequence window it is replacing. If keepLength is FALSE, this replacement method can modify the length of \(x\), depending on how the length of the left subsequence window compares to the length of value.

\section*{Logical Data Methods}

In the code snippets below, x is an Rle object:
! x : Returns logical negation (NOT) of x .
which \((x)\) : Returns an integer vector representing the TRUE indices of \(x\).

\section*{Numerical Data Methods}

In the code snippets below, x is an Rle object:
diff(x, lag = 1, differences = 1: Returns suitably lagged and iterated differences of \(x\).
lag An integer indicating which lag to use.
differences An integer indicating the order of the difference.
pmax(..., na.rm = FALSE), pmax.int(..., na.rm = FALSE): Parallel maxima of the Rle input values. Removes NAs when na.rm = TRUE.
pmin(..., na.rm = FALSE), pmin.int(..., na.rm = FALSE): Parallel minima of the Rle input values. Removes NAs when na.rm = TRUE.
mean ( \(x\), na. rm \(=\) FALSE) :Calculates the mean of \(x\). Removes NAs when na. rm \(=\) TRUE.
\(\operatorname{var}(\mathrm{x}, \mathrm{y}=\mathrm{NULL}, \mathrm{na} . \mathrm{rm}=\mathrm{FALSE})\) : Calculates the variance of x or covariance of x and \(y\) if both are supplied. Removes NAs when na. rm \(=\) TRUE.
cov(x, y, use = "everything"), cor(x, y, use = "everything"): Calculates the covariance and correlation respectively of Rle objects \(x\) and \(y\). The use argument is an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
sd( \(\mathrm{x}, \mathrm{na} . \mathrm{rm}=\mathrm{FALSE}\) ): Calculates the standard deviation of x . Removes NAs when na.rm = TRUE.
median(x, na.rm = FALSE): Calculates the median of x . Removes NAs when na.rm \(=\) TRUE.
quantile(x, probs \(=\) seq(0, 1, 0.25), na.rm \(=\) FALSE, names \(=\) TRUE, type \(=7, \ldots\) ): Calculates the specified quantiles of \(x\).
probs A numeric vector of probabilities with values in \([0,1]\).
na. rm If TRUE, removes NAs from \(x\) before the quantiles are computed.
names If TRUE, the result has names describing the quantiles.
type An integer between 1 and 9 selecting one of the nine quantile algorithms detailed in quantile.
... Further arguments passed to or from other methods.
\(\operatorname{mad}(x\), center \(=\) median \((x)\), constant \(=1.4826\), na.rm \(=\mathrm{FALSE}\), low \(=\) FALSE, high = FALSE): Calculates the median absolute deviation of x .
center The center to calculate the deviation from.
constant The scale factor.
na. rm If TRUE, removes NAs from \(x\) before the mad is computed.
low If TRUE, compute the 'lo-median'.
high If TRUE, compute the 'hi-median'.
\(\operatorname{IQR}(\mathrm{x}, \mathrm{na} . \mathrm{rm}=\mathrm{FALSE}):\) Calculates the interquartile range of x .
na.rm If TRUE, removes NAs from \(x\) before the IQR is computed.
smoothEnds \((y, k=3)\) : Smooth end points of an Rle \(y\) using subsequently smaller medians and Tukey's end point rule at the very end.
k An integer indicating the width of largest median window; must be odd.
runmean ( \(\mathrm{x}, \mathrm{k}\), endrule \(=\mathrm{c}(\) "drop", "constant") ): Calculates the means for fixed width running windows across x .
\(k\) An integer indicating the fixed width of the running window. Must be odd when endrule == "constant".
endrule A character string indicating how the values at the beginning and the end (of the data) should be treated.
"drop" do not extend the running statistics to be the same length as the underlying vectors;
"constant" copies running statistic to the first values and analogously for the last ones making the smoothed ends constant;
runmed (x, k, endrule = c("median", "keep", "drop", "constant")):Calculates the medians for fixed width running windows across x .
\(k\) An integer indicating the fixed width of the running window. Must be odd when endrule != "drop".
endrule A character string indicating how the values at the beginning and the end (of the data) should be treated.
"keep" keeps the first and last \(k_{2}\) values at both ends, where \(k_{2}\) is the half-bandwidth \(\mathrm{k} 2=\mathrm{k}\) \%/\% 2, i.e., \(\mathrm{y}[\mathrm{j}]=\mathrm{x}[\mathrm{j}]\) for \(j \in\left\{1, \ldots, k_{2} ; n-k_{2}+1, \ldots, n\right\} \mathrm{j}=\) \(1, . ., \mathrm{k} 2\) and (n-k2+1),..,n;
"constant" copies the running statistic to the first values and analogously for the last ones making the smoothed ends constant;
"median" the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey's robust end-point rule is applied, see smoothEnds.
runsum(x, \(k\), endrule \(=c(" d r o p ", ~ " c o n s t a n t ")):\) Calculates the sums for fixed width running windows across x .
\(k\) An integer indicating the fixed width of the running window. Must be odd when endrule == "constant".
endrule A character string indicating how the values at the beginning and the end (of the data) should be treated.
"drop" do not extend the running statistics to be the same length as the underlying vectors;
"constant" copies running statistic to the first values and analogously for the last ones making the smoothed ends constant;
runwtsum(x, \(k\), wt, endrule \(=c(" d r o p ", ~ " c o n s t a n t ")):\) Calculates the sums for fixed width running windows across x .
\(k\) An integer indicating the fixed width of the running window. Must be odd when endrule == "constant".
wt A numeric vector of length \(k\) that provides the weights to use.
endrule A character string indicating how the values at the beginning and the end (of the data) should be treated.
"drop" do not extend the running statistics to be the same length as the underlying vectors;
"constant" copies running statistic to the first values and analogously for the last ones making the smoothed ends constant;
rung(x, \(k, i, e n d r u l e=c(" d r o p ", ~ " c o n s t a n t ")): ~ C a l c u l a t e s ~ t h e ~ o r d e r ~ s t a t i s-~\) tic for fixed width running windows across \(x\).
\(k\) An integer indicating the fixed width of the running window. Must be odd when endrule == "constant".
i An integer indicating which order statistic to calculate.
endrule A character string indicating how the values at the beginning and the end (of the data) should be treated.
"drop" do not extend the running statistics to be the same length as the underlying vectors;
"constant" copies running statistic to the first values and analogously for the last ones making the smoothed ends constant;

\section*{Character Data Methods}

In the code snippets below, x is an Rle object:
nchar(x, type = "chars", allowNA = FALSE): Returns an integer Rle representing the number of characters in the corresponding values of x .
type One of c("bytes", "chars", "width").
allowNA Should NA be returned for invalid multibyte strings rather than throwing an error?
substr(x, start, stop), substring(text, first, last = 1000000L):Re-
turns a character or factor Rle containing the specified substrings beginning at start/first and ending at stop/last.
chartr (old, new, x): Returns a character or factor Rle containing a translated version of \(x\).
old A character string specifying the characters to be translated.
new A character string specifying the translations.
tolower (x) : Returns a character or factor Rle containing a lower case version of \(x\).
toupper ( x ) : Returns a character or factor Rle containing an upper case version of x
sub(pattern, replacement, \(x\), ignore.case = FALSE, perl = FALSE, fixed
\(=\) FALSE, useBytes = FALSE) : Returns a character or factor Rle containing replacements based on matches determined by regular expression matching. See sub for a description of the arguments.
gsub (pattern, replacement, \(x\), ignore.case \(=\) FALSE, perl = FALSE, fixed
\(=\) FALSE, useBytes = FALSE): Returns a character or factor Rle containing replacements based on matches determined by regular expression matching. See gsub for a description of the arguments.
paste(..., sep = " ", collapse = NULL): Returns a character or factor Rle containing a concatenation of the values in . . ..

\section*{Factor Data Methods}

In the code snippets below, \(x\) is an Rle object:
levels (x), levels (x) <- value: Gets and sets the factor levels, respectively.
nlevels (x): Returns the number of factor levels.

RleViews-class The RleViews class

\section*{Description}

The RleViews class is the basic container for storing a set of views (start/end locations) on the same Rle object.

\section*{Details}

An RleViews object contains a set of views (start/end locations) on the same Rle object called "the subject vector" or simply "the subject". Each view is defined by its start and end locations: both are integers such that start <=end. An RleViews object is in fact a particular case of a Views object (the RleViews class contains the Views class) so it can be manipulated in a similar manner: see ?Views for more information. Note that two views can overlap and that a view can be "out of limits" i.e. it can start before the first element of the subject or/and end after its last element.

vec <- Rle(sample(0:2, 20, replace = TRUE))
vec
Views(vec, vec > 0)

```
```

RleViewsList-class List of RleViews

```

\section*{Description}

An extension of RangesList that holds only RleViews objects. Useful for storing coverage vectors over a set of spaces (e.g. chromosomes), each of which requires a separate RleViews object. As a Sequence, RleViewsList may be annotated with its universe identifier (e.g. a genome) in which all of its spaces exist.

\section*{Details}

For more information on methods available for RleViewsList objects consult the man pages for RangesList and Views-utils.

\section*{Constructor}

RleViewsList(..., rleList, rangesList, universe = NULL): Either ... or the rleList/rangesList couplet provide the RleViews for the list. If . . . is provided, each of these arguments must be RleViews objects. Alternatively, rleList and rangesList accept Rle and Ranges objects respectively that are meshed together for form the RleViewsList. The universe is specified by the universe parameter, which should be a single string or NULL, to leave unspecified.
Views(subject, start=NULL, end=NULL, width=NULL, names=NULL): Same as RleViewsList(rleList \(=\) subject, rangesList \(=\) start).

\section*{Coercion}

In the code snippets below, from is an RleViewsList object:
as(from, "IRangesList"): Creates a CompressedIRangesList object containing the view locations in from.
as (from, "CompressedIRangesList"): Creates a CompressedIRangesList object containing the view locations in from.
as (from, "SimpleIRangesList"): Creates a SimpleIRangesList object containing the view locations in from.

Sequence-class Sequence objects

```

\section*{Description}

The Sequence virtual class serves as the heart of the IRanges package and has over 90 subclasses. It serves a similar role as vector in base R. The Sequence class includes three slots: element Type, metadata (via extension of the Annotated class), and elementMetadata. Their purpose is defined below.

The element Type slot is the preferred location for Sequence subclasses to store the type of data represented in the sequence. It is designed to take a character of length 1 representing the class of the sequence elements. While the Sequence class performs no validity checking based on element Type, if a subclass expects elements to be of a given type, that subclass is expected to perform the necessary validity checking. For example, the subclass IntegerList has element Type \(=\) "integer" and its validity method checks if this condition is TRUE.

The Sequence class supports the storage of global and element-wise metadata with its metadata and elementMetadata slots. The metadata slot can store a list of metadata pertaining to the whole object and the elementMetadat a slot can store a DataTable (or NULL) for element-wise metadata with a row for each element and a column for each metadata variable.

To be functional, a class that inherits from Sequence must define a length and names methods as well as one or both of the subscript methods " [ [ " and " [ ".

\section*{Accessors}

In the following code snippets, x is a Sequence object.
length ( x ): Get the number of elements in x .
NROW \((x)\) : Defined as length ( x ) for any Sequence object that is not a DataTable object. If x is a DataTable object, then it's defined as nrow ( x )
names (x), names (x) <- value: Get or set the names of the elements in the Sequence.
element Type (x): Get the scalar string naming the class from which all elements must derive. elementLengths \((x)\) : Get the 'length' of each of the elements.
isEmpty (x): Returns a logical indicating either if the sequence has no elements or if all its elements are empty. nlevels (x): Returns the number of factor levels.
metadata (x), metadata(x) <- value: Get or set the list holding arbitrary \(R\) objects as annotations. May be, and often is, empty.
elementMetadata(x), elementMetadata(x) <- value: Get or set the DataTable holding local metadata on each element. The rows are named according to the names of the elements. Optional, may be NULL.
values(x), values(x) <- value: Alternative to elementMetadata functions.

\section*{Subsetting}

In the code snippets below, \(x\) is a Sequence object or regular \(R\) vector object. The \(R\) vector object methods for window and seqselect are defined in this package and the remaining methods are defined in base \(R\).
\(x[i, d r o p=T R U E]:\) If defined, returns a new Sequence object made of selected elements i, which can be missing; an NA-free logical, numeric, or character vector; or a logical Rle object. The drop argument specifies whether or not to coerce the returned sequence to a standard vector.
\(x[i] \quad\) <- value: Equivalent to seqselect(x, i) <- value.
window (x, start \(=\) NA, end \(=N A\), width \(=N A\), frequency \(=\) NULL, delta
\(=\) NULL, . . .) : Extract the subsequence window from the Sequence object using:
start, end, width The start, end, or width of the window. Two of the three are required.
frequency, delta Optional arguments that specify the sampling frequency and increment within the window.
In general, this is more efficient than using " [ " operator.
window(x, start = NA, end = NA, width = NA, keepLength = TRUE) <- value:
Replace the subsequence window specified on the left (i.e. the subsequence in x specified by start, end and width) by value. value must either be of class class(x), belong to a subclass of class (x), be coercible to class (x), or be NULL. If keepLength is TRUE, the elements of value are repeated to create a Sequence with the same number of elements as the width of the subsequence window it is replacing. If keepLength is FALSE, this replacement method can modify the length of x , depending on how the length of the left subsequence window compares to the length of value.
seqselect (x, start=NULL, end=NULL, width=NULL): Similar to window, except that multiple consecutive subsequences can be requested for concatenation. As such two of the three start, end, and width arguments can be used to specify the consecutive subsequences. Alternatively, start can take a Ranges object or something that can be converted to a Ranges object like an integer vector, logical vector or logical Rle. If the concatenation of the consecutive subsequences is undesirable, consider using Views.
seqselect (x, start=NULL, end=NULL, width=NULL) <- value: Similar to window<, except that multiple consecutive subsequences can be replaced by a value whose length is a divisor of the number of elements it is replacing. As such two of the three start, end, and width arguments can be used to specify the consecutive subsequences. Alternatively, start can take a Ranges object or something that can be converted to a Ranges object like an integer vector, logical vector or logical Rle.
head ( \(x, n=6 L\) ): If \(n\) is non-negative, returns the first \(n\) elements of the Sequence object. If \(n\) is negative, returns all but the last abs ( \(n\) ) elements of the Sequence object.
tail ( \(x, n=6 L\) ): If \(n\) is non-negative, returns the last \(n\) elements of the Sequence object. If \(n\) is negative, returns all but the first abs ( \(n\) ) elements of the Sequence object.
rev (x): Return a new Sequence object made of the original elements in the reverse order.
rep (x, times, length.out, each), rep.int ( \(x\), times): Repeats the values in \(x\) through one of the following conventions:
times Vector giving the number of times to repeat each element if of length length (x), or to repeat the whole vector if of length 1.
length. out Non-negative integer. The desired length of the output vector.
each Non-negative integer. Each element of x is repeated each times.
subset ( \(x\), subset): Return a new Sequence object made of the subset using logical vector subset, where missing values are taken as FALSE.

\section*{Element extraction (list style)}

In the code snippets below, x is a Sequence object.
\(x[[i]]\) : If defined, return the selected element \(i\), where \(i\) is an numeric or character vector of length 1.
x \$name: Similar to \(\mathrm{x}[\) [name] ], but name is taken literally as an element name.

\section*{Combining}

In the code snippets below, x is a Sequence object.
\(\mathrm{c}(\mathrm{x}, \ldots .\).\() : Combine \mathrm{x}\) and the Sequence objects in . . . together. Any object in . . . must belong to the same class as \(x\), or to one of its subclasses, or must be NULL. The result is an object of the same class as \(x\).
append(x, values, after = length(x)): Insert the Sequence values onto x at the position given by after. values must have an element Type that extends that of x .

\section*{Looping}

In the code snippets below, x is a Sequence object.
lapply (X, FUN, . . .) : Like the standard lapply function defined in the base package, the lapply method for Sequence objects returns a list of the same length as \(X\), with each element being the result of applying FUN to the corresponding element of X .
sapply(X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE):Like the standard sapply function defined in the base package, the sapply method for Sequence objects is a user-friendly version of lapply by default returning a vector or matrix if appropriate.
```

mapply(FUN, ..., MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE):

```

Like the standard mapply function defined in the base package, the mapply method for Se quence objects is a multivariate version of sapply.
tapply (X, INDEX, FUN = NULL, ..., simplify = TRUE): Like the standardtapply function defined in the base package, the tapply method for Sequence objects applies a function to each cell of a ragged array, that is to each (non-empty) group of values given by a unique combination of the levels of certain factors.
endoapply (X, FUN, ...) : Similar to lapply, but performs an endomorphism, i.e. returns an object of class (X).
mendoapply (FUN, ..., MoreArgs = NULL): Similar to mapply, but performs an endomorphism across multiple objects, i.e. returns an object of class (list (...) [ [1] ]).
shiftApply(SHIFT, X, Y, FUN, ..., OFFSET = OL, simplify = TRUE, verbose
= FALSE) : Let i be the indices in SHIFT, X_i = window (X, 1 + OFFSET, length(X)
- SHIFT[i]), andY_i = window(Y, 1 + SHIFT[i], length(Y) - OFFSET).

Calculates the set of FUN (X_i, Y_i, ...) values and return the results in a convenient form:

SHIFT A non-negative integer vector of shift values.
\(\mathrm{X}, \mathrm{Y}\) The Sequence or R vector objects to shift.
FUN The function, found via match. fun, to be applied to each set of shifted vectors.
... Further arguments for FUN.
OFFSET A non-negative integer offset to maintain throughout the shift operations.
simplify A logical value specifying whether or not the result should be simplified to a vector or matrix if possible.
verbose A logical value specifying whether or not to print the \(i\) indices to track the iterations.
aggregate(x, by, FUN, start = NULL, end = NULL, width = NULL, frequency
= NULL, delta = NULL, ..., simplify = TRUE)): Generates summaries on
the specified windows and returns the result in a convenient form:
by An object with start, end, and width methods.
FUN The function, found via match. fun, to be applied to each window of x .
start, end, width the start, end, or width of the window. If by is missing, then must supply two of the three.
frequency, delta Optional arguments that specify the sampling frequency and increment within the window.
... Further arguments for FUN.
simplify A logical value specifying whether or not the result should be simplified to a vector or matrix if possible.

\section*{Coercion}

In the code snippets below, x is a Sequence object.
as.env(x, enclos = parent.frame()): Creates an environment from x with a symbol for each names ( x ). The values are not actually copied into the environment. Rather, they are dynamically bound using makeActiveBinding. This prevents unnecessary copying of the data from the external vectors into R vectors. The values are cached, so that the data is not copied every time the symbol is accessed.
as.list(x, ...), as (from, "list"): Turns xinto a standard list.
stack(x, indName = "space", valuesName = "values"): As with stack on a list, constructs a DataFrame with two columns: one for the unlisted values, the other indicating the name of the element from which each value was obtained. indName specifies the column name for the index (source name) column and valuesName specifies the column name for the values.

\section*{Functional Programming}

The R base package defines some Higher-Order functions that are commonly found in Functional Programming Languages. See ?Reduce for the details, and, in particular, for a description of their arguments. The IRanges package provides methods for Sequence objects, so, in addition to be a vector, the x argument can also be a Sequence object.

Reduce(f, x, init, right = FALSE, accumulate = FALSE): Uses abinary function to successively combine the elements of \(x\) and a possibly given initial value. See ?Reduce (in the base package) for the details.

Filter ( \(f\), x): Extracts the elements of x for which function f is TRUE. See ?Filter (in the base package) for the details.

Find(f, x, right = FALSE, nomatch = NULL): Extracts the first or last such element in \(x\). See ?Find (in the base package) for the details.

Map (f, ....): Applies a function to the corresponding elements of given Sequence objects. See ?Map (in the base package) for the details.

Position(f, x, right = FALSE, nomatch = NA_integer_): Extracts the first or last such position in \(x\). See ?Position (in the base package) for the details.

\section*{Evaluating}

In the code snippets below, envir and data are Sequence objects.
eval(expr, envir, enclos = parent.frame()): Converts the Sequence object specified in envir to an environment using as.env, with enclos as its parent, and then evaluates expr within that environment.
with(data, expr, ...): Equivalent to eval(quote(expr), data, ...).

SimpleList-class Simple and Compressed List Classes

\section*{Description}

The (non-virtual) SimpleList and (virtual) CompressedList classes extend the Sequence virtual class.

\section*{Details}

The SimpleList and CompressedList classes provide an implementation that subclasses can easily extend. The underlying storage in a SimpleList subclass is a list object. The underlying storage in a CompressedList object is a virtually partitioned vector-like object. For more information on the available methods, see the Sequence man page.

\section*{Constructor}

The SimpleList class constructor is used to create SimpleList objects:
SimpleList (...) : takes possibly named objects as elements for the new SimpleList object.

\section*{Coercion}

In the following code snippets, x is a SimpleList or CompressedList object.
as.list ( x ) : Copies the elements of x into a new R list object.
unlist(x, recursive = TRUE, use.names = TRUE):Concatenates the elements of \(x\) into a single element Type (x) object.

\section*{Subsetting}

In the following code snippets, x is a SimpleList or CompressedList object.
\(\mathrm{x}[\mathrm{i}]\) : In addition to normal usage, the i parameter can be a RangesList, logical RleList, LogicalList, or IntegerList object to perform subsetting within the list elements rather than across them.
\(\mathrm{x}[\mathrm{i}]<-\) value: In addition to normal usage, the i parameter can be a RangesList, logical RleList, LogicalList, or IntegerList object to perform subsetting within the list elements rather than across them.
seqselect(x, start=NULL, end=NULL, width=NULL): In addition to normal usage, the start parameter can be a RangesList, logical RleList, LogicalList, or IntegerList object to perform sequence extraction within the list elements rather than across them.
seqselect(x, start=NULL, end=NULL, width=NULL) <- value: In addition to normal usage, the start parameter can be a RangesList, logical RleList, LogicalList, or IntegerList object to perform sequence replacement within the list elements rather than across them.

\section*{Looping}

In the following code snippets, x is a SimpleList or CompressedList object.
```

aggregate(x, by, FUN, start = NULL, end = NULL, width = NULL, frequency
= NULL, delta = NULL, ..., simplify = TRUE)):In addition to normal us-
age, the by parameter can be a RangesList to aggregate within the list elements rather
than across them. When by is a RangesList, the output is either a SimpleAtomicList
object, if possible, or a SimpleList object, if not.

```

```

Views-class Views objects

```

\section*{Description}

The Views virtual class is a general container for storing a set of views on an arbitrary Sequence object, called the "subject".
Its primary purpose is to introduce concepts and provide some facilities that can be shared by the concrete classes that derive from it.

Some direct subclasses of the Views class are: XIntegerViews, RleViews, XStringViews (defined in the Biostrings package), etc...

\section*{Constructor}

Views(subject, start=NULL, end=NULL, width=NULL, names=NULL):This constructor is a generic function with dispatch on argument subject. Specific methods must be defined for the subclasses of the Views class. For example a method for XString subjects is defined in the Biostrings package that returns an XStringViews object. There is no default method.

The treatment of the start, end and width arguments is the same as with the IRanges constructor, except that, in addition, Views allows start to be a Ranges object. With this feature, Views(subject, IRanges(my_starts, my_ends, my_widths, my_names)) and Views (subject, my_starts, my_ends, my_widths, my_names) are equivalent (except when my_starts is itself a Ranges object).

\section*{Coercion}

In the code snippets below, from is a Views object:
as (from, "IRanges"): Creates an IRanges object containing the view locations in from.

\section*{Accessor-like methods}

All the accessor-like methods defined for IRanges objects work on Views objects. In addition, the following accessors are defined for Views objects:
subject (x) : Return the subject of the views.

\section*{Subsetting and appending}
" [", c and " [ [" work on a Views object. The first two operations are just inherited from the IRanges class but now they return a Views object. However, the " [ [ " method for Views objects has a different semantic than the method for IRanges objects.
\(x[[i]]:\) Extracts the view selected by i as an object of the same class as subject(x). Subscript i can be a single integer or a character string. The result is the subsequence of subject(x) defined by window (subject(x), start=start(x)[i], end=end(x)[i]) or an error if the view is "out of limits" (i.e. start(x) [i] < 1 or end(x) [i] > length (subject(x))).

\section*{Other methods}
trim(x, use.names=TRUE): Equivalent to restrict(x, start=1L, end=length(subject(x)), keep.all.ranges=TRUE, use.names=use.names).
subviews(x, start=NA, end=NA, width=NA, use.names=TRUE):start,end, and width arguments must be vectors of integers, eventually with NAs, that contain coordinates relative to the current ranges. Equivalent to trim (narrow (x, start=start, end=end, width=width, use.names=use.names)).
gaps (x, start=NA, end=NA): start and end can be single integers or NAs. The gap extraction will be restricted to the window specified by start and end. start=NA and end=NA are interpreted as start=1 and end=length (subject (x)), respectively, so, if start and end are not specified, then gaps are extracted with respect to the entire subject.
```

successiveViews(subject, width, gapwidth=0, from=1): Equivalent to Views(subject,

``` successiveIRanges(width, gapwidth, from)). See ?successiveIRanges for a description of the width, gapwidth and from arguments.

Views-utils Utility functions and numeric summary of Views of numerics

\section*{Description}

The slice function creates a Views object that contains the indices where the data are within the specified bounds.
The viewMins, viewMaxs, viewSums, viewMeans functions calculate the minima, maxima, sums, and means on views respectively.

\section*{Usage}
```

    viewApply(X, FUN, ..., simplify = TRUE)
    slice(x, lower=-Inf, upper=Inf, ...)
    ## S4 method for signature 'Rle':
    slice(x, lower=-Inf, upper=Inf,
includeLower=TRUE, includeUpper=TRUE,
rangesOnly = FALSE)
viewMins(x, na.rm=FALSE)
viewMaxs(x, na.rm=FALSE)
viewSums(x, na.rm=FALSE)
viewMeans(x, na.rm=FALSE)
viewWhichMins(x, na.rm=FALSE)
viewWhichMaxs(x, na.rm=FALSE)
viewRangeMins(x, na.rm=FALSE)
viewRangeMaxs(x, na.rm=FALSE)

```

\section*{Arguments}

X
FUN
. . . Additional arguments to be passed on.
```

simplify A logical value specifying whether or not the result should be simplified to a
vector or matrix if possible.
x An Rle, RleList, XInteger object or an integer vector for slice.
An RleViews, RleViewsList, XIntegerViews object for viewMins, viewMaxs,
viewSums, and viewMeans.
An Rle, RleViewsList, XIntegerViews object for viewWhichMins and viewWhichMaxs.
lower, upper The lower and upper bounds for the slice.
includeLower, includeUpper
Logical indicating whether or not the specified boundary is open or closed.
rangesOnly For Rle and RleList objects, a logical indicating whether or not to drop the
original data from the output.
na.rm Logical indicating whether or not to include missing values in the results.

```

\section*{Details}

The slice function is useful for finding areas of absolute maxima (peaks), absolute minima (troughs), or fluctuations within specified limits.

The viewMins, viewMaxs, viewSums, and viewMeans functions provide efficient methods for calculating the specified numeric summary by performing the looping in compiled code.
The viewWhichMins, viewWhichMaxs, viewRangeMins, and viewRangeMaxs functions provide efficient methods for finding the locations of the minima and maxima.

\section*{Value}

An RleViews object for Rle or an RleViewsList for RleList containing the views when using slice with rangesOnly = FALSE. An IRanges object for Rle or a CompressedIRangesList for RleList containing the ranges when using slice with rangesOnly = TRUE. An XIntegerViews for an XInteger object when using slice.
A vector of length (x) for RleViews and XIntegerViews objects or a SimpleList object of length ( x ) for RleViewsList objects containing the numeric summaries for the views for viewMins, viewMaxs, viewSums, viewMeans, viewWhichMins, and viewWhichMaxs.

An IRanges object for RleViews objects or a SimpleIRangesList for RleViewsList objects containing the location ranges for viewRangeMins and viewRangeMaxs.

slice(coverage(x), lower=2)
slice(coverage(x), lower=2, rangesOnly = TRUE)

```

\section*{XIntegerViews-class}

The XIntegerViews class

\section*{Description}

The XIntegerViews class is the basic container for storing a set of views (start/end locations) on the same XInteger object.

\section*{Details}

An XIntegerViews object contains a set of views (start/end locations) on the same XInteger object called "the subject integer vector" or simply "the subject". Each view is defined by its start and end locations: both are integers such that start <= end. An XIntegerViews object is in fact a particular case of a Views object (the XIntegerViews class contains the Views class) so it can be manipulated in a similar manner: see ?Views for more information. Note that two views can overlap and that a view can be "out of limits" i.e. it can start before the first element of the subject or/and end after its last element.

\section*{Other methods}

In the code snippets below, x , object, e1 and e2 are XIntegerViews objects, and i can be a numeric or logical vector.
\(\mathrm{x}[\mathrm{i}]]\) : Extract a view as an XInteger object. i must be a single numeric value (a numeric vector of length 1). Can't be used for extracting a view that is "out of limits" (raise an error). The returned object has the same XInteger subtype as sub ject ( \(x\) ).
e1 == e2: A vector of logicals indicating the result of the view by view comparison. The views in the shorter of the two XIntegerViews object being compared are recycled as necessary.
e1 != e2: Equivalent to ! (e1 == e2).

\section*{Author(s)}
P. Aboyoun

\section*{See Also}

Views-class, XInteger-class, Views-utils

\section*{Examples}
```

## One standard way to create an XIntegerViews object is to use

## the Views() constructor:

subject <- as(c(45, 67, 84, 67, 45, 78), "XInteger")
v4 <- Views(subject, start=3:0, end=5:8)
v4
subject(v4)
length(v4)
start(v4)
end(v4)
width(v4)

## Attach a comment to views \#3 and \#4:

names(v4)[3:4] <- "out of limits"
names(v4)

## A more programatical way to "tag" the "out of limits" views:

names(v4)[start(v4) < 1 | length(subject(v4)) < end(v4)] <- "out of limits"

## or just:

names(v4)[length(subject(v4)) < width(v4)] <- "out of limits"

## Extract a view as an XInteger object:

v4[[2]]

## It is an error to try to extract an "out of limits" view:

\#v4[[3]] \# Error!

## Here the first view doesn't even overlap with the subject:

subject <- as(c(97, 97, 97, 45, 45, 98), "XInteger")
Views(subject, start=-3:4, end=-3:4 + c(3:6, 6:3))

```

XVector-class XVector objects

\section*{Description}

The XVector virtual class is a general container for storing an "external vector". It inherits from the Sequence, which has a very rich interface.

The following classes derive directly from the XVector class:
The XRaw class is a container for storing an "external raw vector" i.e. an external sequence of bytes (stored as char values at the C level).

The XInteger class is a container for storing an "external integer vector" i.e. an external sequence of integer values (stored as int values at the C level).

The XDouble class is a container for storing an "external double vector" i.e. an external sequence of numeric values (stored as double values at the C level).

Also the XString class from the Biostrings package.
The purpose of the \(\mathrm{X}^{*}\) containers is to provide a "pass by address" semantic and also to avoid the overhead of copying the sequence data when a linear subsequence needs to be extracted.

\section*{Additional Subsetting operations on XVector objects}

In the code snippets below, x is an XVector object.
subseq ( \(x\), start=NA, end=NA, width=NA): Extract the subsequence from x specified by start, end and width. The supplied start/end/width values are solved by a call to solveUserSEW(length(x), start=start, end=end, width=width) and therefore must be compliant with the rules of the SEW (Start/End/Width) interface (see ? solveUserSEW for the details).
A note about performance: subseq does NOT copy the sequence data of an XVector object. Hence it's very efficient and is therefore the recommended way to extract a linear subsequence (i.e. a set of consecutive elements) from an XVector object. For example, extracting a 100 Mb subsequence from Human chromosome 1 (a 250 Mb DNAString object) with subseq is (almost) instantaneous and has (almost) no memory footprint (the cost in time and memory does not depend on the length of the original sequence or on the length of the subsequence to extract).
subseq(x, start=NA, end=NA, width=NA) <- value: Replace the subsequence specified on the left (i.e. the subsequence in \(x\) specified by start, end and width) by value. value must belong to the same class as \(x\), or to one of its subclasses, or must be NULL. This replacement method can modify the length of \(x\), depending on how the length of the left subsequence compares to the length of value. It can be used for inserting elements in x (specify an empty left subsequence for this) or deleting elements from x (use a NULL right value for this). Unlike the extraction method above, this replacement method always copies the sequence data of x (even for XVector objects). NOTE: Only works for XRaw (and derived) objects for now.

```

XVectorList-class XVectorList objects

\section*{Description}

\section*{THIS IS A WORK-IN-PROGRESS!}

An XVectorList object is *conceptually* a list of XVector objects.

\section*{Author(s)}
H. Pages

\section*{See Also}

XVector-class

\section*{coverage \\ Coverage across a set of ranges}

\section*{Description}

Counts the number of times a position is represented in a set of ranges.

\section*{Usage}
```

coverage(x, shift=0L, width=NULL, weight=1L, ...)

```
\#\# S4 method for signature 'RangesList':
coverage (x,
```

shift = structure(rep(list(0L), length(x)), names = names(x)),
width = structure(rep(list(NULL), length(x)), names = names(x)),
weight = structure(rep(list(1L), length(x)), names = names(x)))

```

\section*{Arguments}

X
shift For most methods, an integer vector (recycled to the length of \(x\) ) specifying how each element in \(x\) should be (horizontally) shifted before the coverage is computed. Only shifted indices in the range [1, width] will be included in the coverage calculation. For RangesList and RangedData objects, a list or vector of the same length as \(x\) to be used for the corresponding element in \(x\). In addition for RangedData objects, can also be a character vector of length 1 denoting the column to use in values ( x ).

For most methods, an integer vector specifying how much each element in x counts. For RangesList and RangedData objects, a list or vector of the same length as x to be used for the corresponding element in x .
. . . Further arguments to be passed to or from other methods.

\section*{Value}

For most methods, an Rle object representing the coverage of \(x\). For RangesList and RangedData objects, a SimpleRleList object representing a list of coverage vectors.

An integer value called the "coverage" can be associated to each position in \(x\), indicating how many times this position is covered by the elements contained in x . For example, if x is a Views object, the coverage of a given position in subject \((x)\) is the number of views it belongs to.

mask3 <- Mask(mask.width=29, start=c(7, 12), width=c(2, 4))
mymasks <- append(append(mask1, mask2), mask3)
coverage(mymasks)

```
disjoin

\section*{Description}

Functions for making Ranges disjoint, where no ranges overlap another.

\section*{Usage}
```

disjoin(x, ...)
disjointBins(x, ...)

```

\section*{Arguments}
x
The Ranges instance, possibly overlapping intervals.
. . Additional arguments for methods

\section*{Details}

The disjoin method returns a disjoint Ranges, by finding the union of the end points in x . In other words, the result consists of a range for every interval, of maximal length, over which the set of overlapping ranges in \(x\) is the same and at least of size 1 .
disjointBins segregates \(x\) into a set of bins so that the ranges in each bin are disjoint. Lowerindexed bins are filled first. The method returns an integer vector indicating the bin index for each range.

\section*{Author(s)}
M. Lawrence

\section*{See Also}
reduce for making normal ranges, a subset of disjoint ranges, where there must be a gap of length \(>=1\) between each range.

\section*{Examples}
```

ir <- IRanges(c(1, 1, 4, 10), c(6, 3, 8, 10))
disjoin(ir) \# IRanges(c(1, 4, 7, 10), c(3, 6, 8, 10))
disjointBins(IRanges(1, 5)) \# 1L
disjointBins(IRanges(c(3, 1, 10), c(5, 12, 13))) \# c(2L, 1L, 2L)

```
endoapply

Endomorphisms via application of a function over an object's elements

\section*{Description}

Performs the endomorphic equivalents of lapply and mapply by returning objects of the same class as the inputs rather than a list.

\section*{Usage}
```

endoapply(X, FUN, ...)
mendoapply(FUN, ..., MoreArgs = NULL)

```

\section*{Arguments}
\(X \quad\) a list, data.frame or Sequence object.
FUN the function to be applied to each element of \(X\) (for endoapply) or for the elements in . . . (for mendoapply).
... For endoapply, optional arguments to FUN. For mendoapply, a set of list, data.frame or Sequence objects to compute over.
MoreArgs a list of other arguments to FUN.

\section*{Value}
endoapply returns an object of the same class as \(X\), each element of which is the result of applying FUN to the corresponding element of X .
mendoapply returns an object of the same class as the first object specified in . . ., each element of which is the result of applying FUN to the corresponding elements of . . .

\section*{See Also}
```

lapply,mapply

```

\section*{Examples}
```

a <- data.frame(x = 1:10, y = rnorm(10))
b <- data.frame(x = 1:10, y = rnorm(10))
endoapply(a, function(x) (x - mean(x))/sd(x))
mendoapply(function(e1, e2) (e1 - mean(e1)) * (e2 - mean(e2)), a, b)

```

\section*{nearest Nearest neighbor finding}

\section*{Description}

The nearest, precede and follow methods find nearest neighbors between Ranges instances.

\section*{Usage}
```

nearest(x, subject, ...)
precede(x, subject = x, ...)
follow(x, subject = x, ...)

```

\section*{Arguments}
\(x \quad\) The query Ranges instance.
subject The subject Ranges instance, within which the nearest neighbors are found. Can be missing, in which case the query, x , is also the subject.
. . Additional arguments for methods

\section*{Details}
nearest is the conventional nearest neighbor finder and returns a integer vector containing the index of the nearest neighbor range in sub ject for each range in \(x\). If there is no nearest neighbor (if subject is empty), NA's are returned.

The algorithm is roughly as follows, for a range xi in x :
1. Find the ranges in subject that overlap xi. If a single range si in subject overlaps \(x i\), si is returned as the nearest neighbor of xi. If there are multiple overlaps, one of the overlapping ranges is chosen arbitrarily.
2. If no ranges in subject overlap with xi, then the range in subject with the shortest distance from its end to the start \(x i\) or its start to the end of \(x i\) is returned.
precede returns an integer vector of the index of range in subject that ends before and closest to the start of each range in \(x\). Note that any overlapping ranges are excluded. NA is returned when there are no qualifying ranges in subject.
follow is the opposite of precede: it returns the index of the range in sub ject that starts after and closest to the end of each range in \(x\).

\section*{Author(s)}
M. Lawrence

\section*{See Also}
findOverlaps for finding just the overlapping ranges.

follow(query, IRanges()) \# rep(NA_integer_, 3)
follow(query) \# c(NA, NA, 2L)

```
read. Mask Read a mask from a file

\section*{Description}
read.agpMask and read.gapMask extract the AGAPS mask from an NCBI "agp" file or a UCSC "gap" file, respectively.
read.liftMask extracts the AGAPS mask from a UCSC "lift" file (i.e. a file containing offsets of contigs within sequences).
read. rmMask extracts the RM mask from a RepeatMasker .out file.
read.trfMask extracts the TRF mask from a Tandem Repeats Finder .bed file.

\section*{Usage}
```

read.agpMask(file, seqname="?", mask.width=NA, gap.types=NULL, use.gap.types=F
read.gapMask(file, seqname="?", mask.width=NA, gap.types=NULL, use.gap.types=F
read.liftMask(file, seqname="?", mask.width=NA)
read.rmMask(file, seqname="?", mask.width=NA, use.IDs=FALSE)
read.trfMask(file, seqname="?", mask.width=NA)

```

\section*{Arguments}
file
seqname

Either a character string naming a file or a connection open for reading.
The name of the sequence for which the mask must be extracted. If no sequence is specified (i.e. seqname="?") then an error is raised and the sequence names found in the file are displayed. If the file doesn't contain any information for the specified sequence, then a warning is issued and an empty mask of width mask.width is returned.
mask.width The width of the mask to return i.e. the length of the sequence this mask will be put on. See ¿MaskCollection-class' for more information about the width of a MaskCollection object.
gap.types NULL or a character vector containing gap types. Use this argument to filter the assembly gaps that are to be extracted from the "agp" or "gap" file based on their type. Most common gap types are "contig", "clone", "centromere", "telomere", "heterochromatin", "short_arm" and "fragment". With gap.types=NULL, all the assembly gaps described in the file are extracted. With gap.types="?", an error is raised and the gap types found in the file for the specified sequence are displayed.
```

use.gap.types

```

Whether or not the gap types provided in the "agp" or "gap" file should be used to name the ranges constituing the returned mask. See ¿IRanges-class ' for more information about the names of an IRanges object.
use.IDs Whether or not the repeat IDs provided in the RepeatMasker .out file should be used to name the ranges constituing the returned mask. See ¿IRangesclass' for more information about the names of an IRanges object.

## Before you can extract a mask with read.rmMask() or read.trfMask(), you
## need to know the length of the sequence that you're going to put the
## mask on:
if (interactive()) {
    library(BSgenome.Celegans.UCSC.ce2)
    chrM_length <- seqlengths(Celegans)[["chrM"]]
    ## Read the RepeatMasker .out file for chrM in ce2:
    file3 <- system.file("extdata", "ce2chrM.fa.out", package="IRanges")
    RMmask <- read.rmMask(file3, seqname="chrM", mask.width=chrM_length)
    RMmask
    ## Read the Tandem Repeats Finder .bed file for chrM in ce2:
    file4 <- system.file("extdata", "ce2chrM.bed", package="IRanges")
    TRFmask <- read.trfMask(file4, seqname="chrM", mask.width=chrM_length)
    TRFmask
    desc(TRFmask) <- paste(desc(TRFmask), "[period<=12]")
    TRFmask
    ## Put the 2 masks on chrM:
    chrM <- Celegans$chrM
    masks(chrM) <- RMmask # this would drop all current masks, if any
    masks(chrM) <- append(masks(chrM), TRFmask)
    chrM
}
```

## Description

This operation is not intended to be used directly.

## Usage

```
reverse(x, ...)
```

## Arguments

$x \quad$ An IRanges object.
. . . Additional arguments to be passed to or from methods.

## Value

An object of the same class and length as the original object.

## Examples

```
## WARNING: The examples here are not relevant anymore and will be
## updated soon.
x <- IRanges(start=c(-2L, 6L, 9L, -4L, 1L, 0L, -6L, 10L),
    width=c( 5L, 0L, 6L, 1L, 4L, 3L, 2L, 3L))
reverse(x, start=-6, end=20)
## When omitted, 'start' and 'end' are considered to be 'min(start(x))'
## and 'max(end(x))', respectively:
reverse(x)
reverse(shift(x, 2), start=-6, end=20)
reverse(restrict(x, 1, 10), start=-6, end=20)
reverse(reduce(x), start=-6, end=20)
reverse(gaps(x, start=-6, end=20), start=-6, end=20)
mask1 <- Mask(mask.width=29, start=c(11, 25, 28), width=c(5, 2, 2))
mask2 <- Mask(mask.width=29, start=c(3, 10, 27), width=c(5, 8, 1))
mask3 <- Mask(mask.width=29, start=c(7, 12), width=c(2, 4))
mymasks <- append(append(mask1, mask2), mask3)
reverse(mymasks)
```

runstat

Fixed width running window summaries across vector-like objects

## Description

The runsum, runmean, runwt sum, runq functions calculate the sum, mean, weighted sum, and order statistics for fixed width running windows.

## Usage

```
runsum(x, k, endrule = c("drop", "constant"))
runmean(x, k, endrule = c("drop", "constant"))
runwtsum(x, k, wt, endrule = c("drop", "constant"))
runq(x, k, i, endrule = c("drop", "constant"))
```

## Arguments

x
k
wt
i
endrule

The data object.
An integer indicating the fixed width of the running window. Must be odd when endrule == "constant".

A numeric vector of length $k$ that provides the weights to use.
An integer indicating which order statistic to calculate.
A character string indicating how the values at the beginning and the end (of the data) should be treated.
"drop" do not extend the running statistics to be the same length as the underlying vectors;
"constant" copies running statistic to the first values and analogously for the last ones making the smoothed ends constant;

## Details

The runsum, runmean, runwt sum, and runq functions provide efficient methods for calculating the specified numeric summary by performing the looping in compiled code.

## Value

An object of the same class as x .

## Author(s)

## P. Aboyoun

## See Also

runmed, Rle-class, RleList-class

## Examples

$x<-\operatorname{Rle}(1: 10,1: 10)$
runsum ( $\mathrm{x}, \mathrm{k}=3$ )
runsum ( $\mathrm{x}, \mathrm{k}=3$, endrule $=$ "constant")
runmean ( $\mathrm{x}, \mathrm{k}=3$ )
runwtsum ( $\mathrm{x}, \mathrm{k}=3$, wt $=c(0.25,0.5,0.25)$ )
rung(x, $k=5, i=3$, endrule $=$ "constant")

## Description

Gets and sets the score of an object.

## Usage

```
score(x, ...)
score(x, ...) <- value
```

## Arguments

X
value
...
.
$\qquad$

An object to get or set the score value of.
A new score value.
Additional arguments.

```
seqapply Apply function and cast to Sequence
```

## Description

The seqapply family of functions behaves much like the existing lapply family, except the return value is cast to a Sequence subclass. This facilitates constraining computation to the Sequence framework across iteration and (for seqsplit) splitting.

## Usage

```
seqapply(X, FUN, ...)
mseqapply(FUN, ..., MoreArgs = NULL, USE.NAMES = TRUE)
tseqapply(X, INDEX, FUN = NULL, ...)
seqsplit(x, f, drop = FALSE)
```

## Arguments

X The object over which to iterate, usually a vector or Sequence
FUN $\quad$ The function that is applied to each element of $X$
MoreArgs Additional arguments to FUN that are treated like scalars
USE.NAMES Whether the return values should inherit names from one of the arguments
INDEX A list of factors to split X into subsets, each of which is passed in a separate invocation of FUN
x Like X above
f A factor or list of factors
drop Whether to drop empty elements from the returned list
... Extra arguments to pass to FUN

## Details

These functions should be used just like their base equivalent:

```
seqapply => lapply
mseqapply => mapply
tseqapply => tapply
seqsplit => split
```

The only difference is that the result is cast to a Sequence object. The casting logic simply looks for a common class from which all returned values inherit. It then checks for the existence of a function of the form ClassList where Class is the name of the class. If such a function is not found, the search proceeds up the hierarchy of classes. An error is thrown when hierarchy is exhausted. If ClassList is found, it is called with the list of return values as its only argument, under the assumption that a Sequence-derived instance will be constructed.

## Value

A Sequence object

## Author(s)

Michael Lawrence

## Examples

```
starts <- IntegerList(c(1, 5), c(2, 8))
ends <- IntegerList(c(3, 8), c(5, 9))
rangesList <- mseqapply(IRanges, starts, ends)
rangeDataFrame <- stack(rangesList, "space", "ranges")
dataFrameList <- seqsplit(rangeDataFrame, rangeDataFrame$space)
starts <- seqapply(dataFrameList[,"ranges"], start)
```

```
strutils Low-level string utilities
```

## Description

Some low-level string utilities that operate on ordinary character vectors. For more advanced string manipulations, see the Biostrings package.

## Usage

```
strsplitAsListOfIntegerVectors(x, sep=",")
```

## Arguments

$x \quad$ A character vector where each element is a string containing comma-separated decimal integer values.
sep The value separator character.

## Value

A list of integer vectors. The list is of the same length as the input.

## Note

strsplitAsListOfIntegerVectors is similar to the strsplitAsListOfIntegerVectors2 function shown in the Examples section below, except that the former generally raises an error where the latter would have inserted an NA in the returned object. More precisely:

- The latter accepts NAs in the input, the former doesn't (raises an error).
- The latter introduces NAs by coercion (with a warning), the former doesn't (raises an error).
- The latter supports "inaccurate integer conversion in coercion" when the value to coerce is > INT_MAX (then it's coerced to INT_MAX), the former doesn't (raises an error).
- The latter coerces non-integer values (e.g. 10.3) to an int by truncating them, the former doesn't (raises an error).

When it fails, strsplitAsListOfIntegerVectors will print an informative error message. Finally, strsplitAsListOfIntegerVectors is faster and uses much less memory than strsplitAsListofintegerVectors2.

## Author(s)

H. Pages

## See Also

```
strsplit
```

## Examples

```
x <- c("1116,0,-19",
            " +55291 , 2476,",
            "19184,4269,5659,6470,6721,7469,14601",
            "7778889, 426900, -4833,5659,6470,6721,7096",
            "19184 , -99999")
y <- strsplitAsListOfIntegerVectors(x)
y
## In normal situations (i.e. when the input is well-formed),
## strsplitAsListOfIntegerVectors() does actually the same as the
## function below but is faster and much more memory efficient:
strsplitAsListOfIntegerVectors2 <- function(x, sep=",")
{
    tmp <- strsplit(x, sep, fixed = TRUE)
    lapply(tmp, as.integer)
}
y2 <- strsplitAsListOfIntegerVectors2(x)
stopifnot(identical(y, y2))
```

updateObject Update an IRanges object from BioC 2.4 to current version

## Description

Updates an old IRanges object to the current version. This updating process is useful when an object has been serialized (e.g., stored to disk) for some time (e.g., months), and the class definition has changed. This change in class definition makes the serialized instance is no longer valid.

## Usage

```
updateObject(object, ..., verbose=FALSE)
```

## Arguments

ob ject Object to be updated, or for slot information to be extracted from.
verbose A logical, indicating whether information about the update should be reported. Use message to report this.
. . . Additional arguments, for use in specific update methods.

## Value

updateObject returns a valid instance of object.
