

MSnbase: labelled and label-free MS2 data pre-processing, visualisation and quantification.

LAURENT GATTO* AND SEBASTIAN GIBB

Computational Proteomics Unit
University of Cambridge, UK

April 22, 2014

This vignette describes the functionality implemented in the MSnbase package. MSnbase aims at (1) facilitating the import, processing, visualisation and quantification of mass spectrometry data into the R environment ([R Development Core Team, 2011](#)) by providing specific data classes and methods and (2) enabling the utilisation of throughput-high data analysis pipelines provided by the Bioconductor ([Gentleman et al., 2004](#)) project.

Keywords: Mass Spectrometry (MS), proteomics, infrastructure, quantitative.

Foreword

MSnbase is under active developed; current functionality is evolving and new features will be added. This software is free and open-source software. If you use it, please support the project by citing it in publications:

Laurent Gatto and Kathryn S. Lilley. *MSnbase - an R/Bioconductor package for isobaric tagged mass spectrometry data visualization, processing and quantitation*. Bioinformatics 28, 288-289 (2011).

You are welcome to contact me for questions, bugs, typos or suggestions about MSnbase. If you wish to reach a broader audience for general questions about proteomics analysis using R, you may want to use the Bioconductor mailing list¹.

¹<https://stat.ethz.ch/mailman/listinfo/bioconductor>

1 Introduction

MSnbase (Gatto and Lilley, 2012) aims at providing a reproducible research framework to proteomics data analysis. It should allow researcher to easily mine mass spectrometry data, explore the data and its statistical properties and visually display these.

MSnbase also aims at being compatible with the infrastructure implemented in Bioconductor, in particular Biobase. As such, classes developed specifically for proteomics mass spectrometry data are based on the `eSet` and `Expression` classes. The main goal is to assure seamless compatibility with existing meta data structure, accessor methods and normalisation techniques.

This vignette illustrates MSnbase utility using a dummy data sets provided with the package without describing the underlying data structures. More details can be found in the package, classes, method and function documentations. A description of the classes is provided in the `MSnbase-development` vignette.

Speed and memory requirements Raw mass spectrometry file are generally several hundreds of MB large and most of this is used for binary raw spectrum data. As such, data containers can easily grow very large and thus require large amounts of RAM. This requirement is being tackled by avoiding to load the raw data into memory and using on-disk random access to the content of `mzXML`/`mzML` data files on demand. When focusing on reporter ion quantitation, a direct solution for this is to trim the spectra using the `trimMz` method to select the area of interest and thus substantially reduce the size of the `Spectrum` objects. This is illustrated in section 6.2 on page 20 of the `MSnbase-demo` vignette.

The independent handling of spectra is ideally suited for parallel processing. The `quantify` method now performs reporter peaks quantitation in parallel. More functions are being updated.

2 Data structure and content

2.1 Importing experiments

MSnbase is able to import raw MS data stored in one of the XML-based formats as well as peak lists in the `mfg` format²

²Mascot Generic Format – http://www.matrixscience.com/help/data_file_help.html#GEN

Raw data The XML-based formats, `mzXML` (Pedrioli et al., 2004), `mzData` (Orchard et al., 2007) and `mzML` (Martens et al., 2010) can be imported with the `readMSData` function, as illustrated below (see `?readMSData` for more details).

```
> file <- dir(system.file(package = "MSnbase", dir = "extdata"),
+             full.names = TRUE, pattern = "mzXML$")
> rawdata <- readMSData(file, msLevel = 2, verbose = FALSE)
```

Either MS1 or MS2 spectra can be loaded at a time by setting the `msLevel` parameter accordingly. In this document, we will use the `itraqdata` data set, provided with `MSnbase`. It includes feature metadata, accessible with the `fData` accessor. The metadata includes identification data for the 55 MS2 spectra.

Peak lists Peak lists can often be exported after spectrum processing from vendor-specific software and are also used as input to search engines. Peak lists in `mgf` format can be imported with the function `readMgfData` (see `?readMgfData` for details) to create experiment objects. Experiments or individual spectra can be exported to an `mgf` file with the `writeMgfData` methods (see `?writeMgfData` for details and examples).

Experiments with multiple runs Although it is possible to load and process multiple files serially and later merge the resulting quantitation data as show in section 11 (page 35), it is also feasible to load several raw data files at once. Here, we report the analysis of an LC-MSMS experiment where 14 liquid chromatography (LC) fractions were loaded using `readMSData` on a 32-cores servers with 128 Gb of RAM. It took about 90 minutes to read the 14 un-centroided `mzXML` raw files (4.9 Gb on disk in total) and create a 3.3 Gb raw data object (an `MSnExp` instance, see next section). Quantitation of 9 reporter ions (`iTRAQ9` object, see 2.4) for 88690 features was performed in parallel on 16 processors and took 76 minutes. The resulting quantitation data was only 22.1 Mb and could easily be further processed and analysed on a standard laptop computer.

See also section 7.2 to import quantitative data stored in spreadsheets into R for further processing using `MSnbase`. The `MSnbase-io` vignette gives a general overview of `MSnbase`'s input/output capabilities.

2.2 MS experiments

Raw data is contained in `MSnExp` objects, that stores all the spectra of an experiment, as defined by one or multiple raw data files.

```
> library("MSnbase")
> itraqdata

Object of class "MSnExp"
  Object size in memory: 1.76 Mb
- - - Spectra data - - -
  MS level(s): 2
  Number of MS1 acquisitions: 1
  Number of MSn scans: 55
  Number of precursor ions: 55
  55 unique MZs
  Precursor MZ's: 401.74 - 1236.1
  MSn M/Z range: 100 2069
  MSn retention times: 19:9 - 50:18 minutes
- - - Processing information - - -
Data loaded: Wed May 11 18:54:39 2011
  MSnbase version: 1.1.22
- - - Meta data - - -
phenoData
  rowNames: 1

X12	chaperone protein DnaK	TAIDDALK
X13	succinyl-CoA synthetase alpha chain	SILINK
X14	NADP-dependent malic enzyme	DFEVVNESDPR

As illustrated above, showing the experiment textually displays it's content:

- Information about the raw data, i.e. the spectra.
- Specific information about the experiment processing³ and package version. This slot can be accessed with the `processingData` method.
- Other meta data, including experimental phenotype, file name(s) used to import the data, protocol data, information about features (individual spectra here) and experiment data. Most of these are implemented as in the `eSet` class and are described in more details in their respective manual pages. See `?MSnExp` and references therein for additional background information.

The experiment meta data associated with an `MSnExp` experiment is of class `MIAPE`. It stores general information about the experiment as well as MIAPE (Minimum Information About a Proteomics Experiment) information ([Taylor et al., 2007, 2008](#)). This meta-data can be accessed with the `experimentData` method. When available, a summary of MIAPE-MS data can be printed with the `msInfo` method. See `?MIAPE` for more details.

2.3 Spectra objects

The raw data is composed of the 55 MS spectra. The spectra are named individually (X1, X10, X11, X12, X13, X14, ...) and stored in a `environment`. They can be accessed individually with `itraqdata[["X1"]]` or `itraqdata[[1]]`,

³this part will be automatically updated when the object is modified with it's *ad hoc* methods, as illustrated later

or as a list with `spectra(itraqdata)`. As we have loaded our experiment specifying `msLevel=2`, the spectra will all be of level 2 (or higher, if available).

```
> sp <- itraqdata[["X1"]]
> sp

Object of class "Spectrum2"
Precursor: 520.8
Retention time: 19:9
Charge: 2
MSn level: 2
Peaks count: 1922
Total ion count: 26413754
```

Attributes of individual spectra or of all spectra of an experiment can be accessed with their respective methods: `precursorCharge` for the precursor charge, `rttime` for the retention time, `mz` for the MZ values, `intensity` for the intensities, ... see the `Spectrum`, `Spectrum1` and `Spectrum2` manuals for more details.

```
> peaksCount(sp)

[1] 1922

> head(peaksCount(itraqdata))

  X1  X10  X11  X12  X13  X14
1922 1376 1571 2397 2574 1829

> rttime(sp)

[1] 1149

> head(rttime(itraqdata))

  X1  X10  X11  X12  X13  X14
1149 1503 1664 1664 1664 1664
```

2.4 Reporter ions

Reporter ions are defined with the `ReporterIons` class. Specific peaks of interest are defined by a MZ value, a width around the expected MZ and a name

(and optionally a colour for plotting, see section 3). `ReporterIons` instances are required to quantify reporter peaks in `MSnExp` experiments. Instances for the most commonly used isobaric tags like iTRAQ 4-plex and 8-plex and TMT tags are already defined in `MSnbase`. See `?ReporterIons` for details about how to generate new `ReporterIons` objects.

```
> iTRAQ4

Object of class "ReporterIons"
iTRAQ4: '4-plex iTRAQ' with 4 reporter ions
- 114.1 +/- 0.05 (red)
- 115.1 +/- 0.05 (green)
- 116.1 +/- 0.05 (blue)
- 117.1 +/- 0.05 (yellow)
```

3 Plotting raw data

3.1 Default plots

Spectra can be plotted individually or as part of (subset) experiments with the `plot` method. Full spectra can be plotted (using `full=TRUE`), specific reporter ions of interest (by specifying with reporters with `reporters=iTRAQ4` for instance) or both (see figure 1).

It is also possible to plot all spectra of an experiment (figure 2). Lets start by subsetting the `itraqdata` experiment using the protein accession numbers included in the feature metadata, and keep the 6 from the *BSA* protein.

```
> sel <- fData(itraqdata)$ProteinAccession == "BSA"
> bsa <- itraqdata[sel]
> bsa

Object of class "MSnExp"
Object size in memory: 0.09 Mb
- - - Spectra data - - -
MS level(s): 2
Number of MS1 acquisitions: 1
Number of MSn scans: 3
Number of precursor ions: 3
3 unique MZs
```

```
> plot(sp, reporters = iTRAQ4, full = TRUE)
```

Figure 1: Raw MS2 spectrum with details about reporter ions.

```
Precursor MZ's: 434.95 - 651.92
MSn M/Z range: 100 1352
MSn retention times: 19:9 - 36:17 minutes
- - - Processing information - - -
Data loaded: Wed May 11 18:54:39 2011
Data [logically] subsetted 3 spectra: Tue Apr 22 03:06:38 2014
MSnbase version: 1.1.22
- - - Meta data - - -
phenoData
  rowNames: 1
  varLabels: sampleNames sampleNumbers
  varMetadata: labelDescription
Loaded from:
  dummyiTRAQ.mzXML
protocolData: none
featureData
  featureNames: X1 X52 X53
  fvarLabels: spectrum ProteinAccession ProteinDescription
             PeptideSequence
```

```
fvarMetadata: labelDescription
experimentData: use 'experimentData(object) '

> as.character(fData(bsa)$ProteinAccession)

[1] "BSA" "BSA" "BSA"
```

These can then be visualised together by plotting the `MSnExp` object, as illustrated on figure 2.

3.2 Customising your plots

The `MSnbase` plot methods have a logical `plot` parameter (default is `TRUE`), that specifies if the plot should be printed to the current device. A plot object is also (invisibly) returned, so that it can be saved as a variable for later use or for customisation.

`MSnbase` uses the `ggplot2` package to generate figures, which can subsequently easily be customised. More details about `ggplot2` can be found in Wickham (2009) (especially chapter 8) and on <http://had.co.nz/ggplot2/>. Finally, if a plot object has been saved in a variable `p`, it is possible to obtain a summary about the object with `summary(p)`. To view the data frame used to generate the plot, use `p@data`.

```
> plot(bsa, reporters = iTRAQ4, full = FALSE) + theme_gray(8)
```

Figure 2: Experiment-wide raw MS2 spectra. The y-axes of the individual spectra are automatically rescaled to the same range. See section 7.4 to rescale peaks identically.

4 Tandem MS identification data

4.1 Adding identification data

MSnbase is able to integrate identification data from `mzIdentML` (Jones et al., 2012) files.

We first load two example files shipped with the `MSnbase` containing raw data (as above) and the corresponding identification results respectively. The raw data is read with the `readMSData`, as demonstrated above. As can be seen, the default feature data only contain spectra numbers⁴.

```
> ## find path to a mzXML file
> quantFile <- dir(system.file(package = "MSnbase", dir = "extdata"),
+                 full.name = TRUE, pattern = "mzXML$")
> ## find path to a mzIdentML file
> identFile <- dir(system.file(package = "MSnbase", dir = "extdata"),
+                 full.name = TRUE, pattern = "mzid$")
> ## create basic MSnExp
> msexp <- readMSData(quantFile, verbose = FALSE)
> head(fData(msexp), n = 2)
```

	spectrum
X1.1	1
X2.1	2

The `addIdentificationData` method takes an `MSnExp` instance (or an `MSnSet` instance storing quantitation data, see section 7.1) as first argument and one or multiple `mzIdentML` file names (as a character vector) as second one and updates the `MSnExp` feature data using the identification data read from the `mzIdentML` file(s).

```
> ## add identification information
> msexp <- addIdentificationData(msexp, filenames = identFile,
+                               verbose = FALSE)
> head(fData(msexp), n = 2)
```

	spectrum	passthreshold	rank	calculatedmasstocharge
X1.1	1	TRUE	1	645
X2.1	2	TRUE	1	547

⁴More data about the spectra is of course available in an `MSnExp` object, as illustrated in the previous sections. See also `?pSet` and `?MSnExp` for more details.

	experimentalmasstocharge	chargestate	ms-gf:denovoscore						
X1.1	645.3741455078125	3	77						
X2.1	546.9586181640625	3	39						
	ms-gf:evaluate	ms-gf:rawscore	ms-gf:specvalue

X2.1	CID	0	IDGQWVTHQWLKK						
	modified	modification	isdecoy	post	pre	end	start		
X1.1	FALSE	NA	FALSE	A	R	186	170		
X2.1	FALSE	NA	FALSE	A	K	62	50		
	accession	length							
X1.1	ECA0984;ECA3829	231							
X2.1	ECA1028	275							
									description
X1.1	DNA mismatch repair protein;acetolactate synthase isozyme III large subunit								
X2.1	2,3,4,5-tetrahydropyridine-2,6-dicarboxylate N-succinyltransferase								
	databaseFile	identFile	npsm						
X1.1	erwinia_carotovora.fasta	2	2						
X2.1	erwinia_carotovora.fasta	2	1						

Finally we can use `idSummary` to summarise the percentage of identified features per quantitation/identification pairs.

```
> idSummary(msexp)

quantFile identFile coverage
1          1          2      0.6
```

4.2 Filtering identification data

One can remove the features that have not been identified using `removeNoId`. This function uses by default the `pepseq` feature variable to search the presence of missing data (NA values) and then filter these non-identified spectra.

```
> fData(msexp)$pepseq

[1] "VESITARHGEVLQLRPK" "IDGQWVTHQWLKK"      NA
[4] NA                  "LVILLFR"
```

```

> msexp <- removeNoId(msexp)
> fData(msexp)$pepseq

[1] "VESITARHGEVLQLRPK" "IDGQWVTHQWLKK"      "LVILLFR"

> idSummary(msexp)

  quantFile identFile coverage
1         1         2         1

```

Similarly, the `removeMultipleAssignment` method can be used to filter out spectra that match peptides that have been assigned to multiple proteins. This function uses by default the `npsm` feature variable.

Note that `removeNoId` and `removeMultipleAssignment` methods can also be called on `MSnExp` instances.

5 Quality control

The current section is not executed dynamically for package size and processing time constraints. The figures and tables have been generated with the respective methods and included statically in the vignette for illustration purposes.

`MSnbase` allows easy and flexible access to the data, which allows to visualise data features to assess its quality. Some methods are readily available, although many QC approaches will be experiment specific and users are encouraged to explore their data.

The `plot2d` method takes one `MSnExp` instance as first argument to produce retention time *vs.* precursor MZ scatter plots. Points represent individual MS2 spectra and can be coloured based on precursor charge (with second argument `z="charge"`), total ion count (`z="ionCount"`), number of peaks in the MS2 spectra (`z="peaks.count"`) or, when multiple data files were loaded, file `z="file"`), as illustrated on figure 3. The lower right panel is produced for only a subset of proteins. See the method documentation for more details.

The `plotDensity` method illustrates the distribution of several parameters of interest (see figure 4). Similarly to `plot2d`, the first argument is an `MSnExp` instance. The second is one of `precursor.mz`, `peaks.count` or `ionCount`, whose density will be plotted. An optional third argument specifies whether the x axes should be logged.

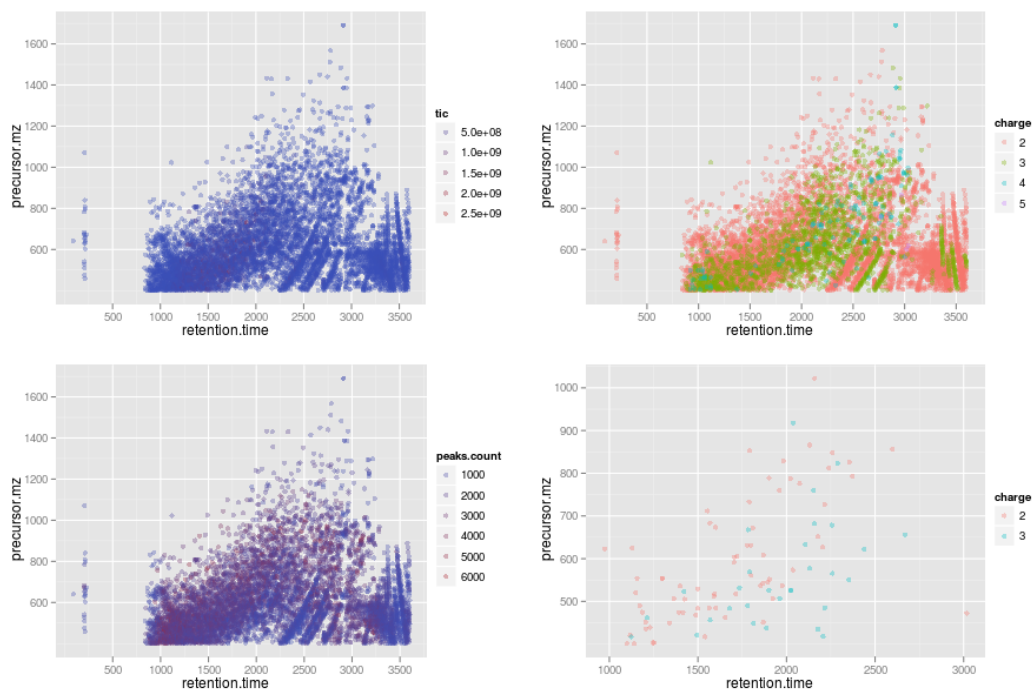

Figure 3: Illustration of the `plot2d` output.

Figure 4: Illustration of the `plotDensity` output.

The `plotMzDelta` method⁵ implements the M/Z delta plot from Foster et al. (2011). The M/Z delta plot illustrates the suitability of MS2 spectra for identification by plotting the M/Z differences of the most intense peaks. The resulting histogram should optimally show outstanding bars at amino acid residue masses. More details and parameters are described in the method documentation (`?plotMzDelta`). Figure 5 has been generated using the PRIDE experiment 12011, as in Foster et al. (2011).

In section 10 on page 34, we illustrate how to assess incomplete reporter ion dissociation.

⁵The code to generate the histograms has been contributed by Guangchuang Yu from Jinan University, China.

Figure 5: Illustration of the `plotMzDelta` output for the PRIDE experiment 12011, as in figure 4A from [Foster et al. \(2011\)](#).

6 Data processing

6.1 Cleaning spectra

There are several methods implemented to perform basic data manipulation. Low intensity peaks can be set to 0 with the `removePeaks` method from spectra or whole experiments. The intensity threshold below which peaks are removed is defined by the `t` parameter. `t` can be specified directly as a numeric. The default value is the character `"min"`, that will remove all peaks equal to the lowest non null intensity in any spectrum. We observe the effect of the `removePeaks` method by comparing total ion count (i.e. the total intensity in a spectrum) with the `ionCount` method before (object `itraqdata`) and after (object `experiment`) for spectrum X55. The respective spectra are shown on figure 6 (page 18).

```
> experiment <- removePeaks(itraqdata, t = 400, verbose = FALSE)
> ## total ion current
> ionCount(itraqdata[["X55"]])

[1] 555409
```

```
> ionCount(experiment[["X55"]])
```

```
[1] 499770
```

Figure 6: Same spectrum before (left) and after setting peaks $j=400$ to 0.

Unlike the name might suggest, the `removePeaks` method does not actually remove peaks from the spectrum; they are set to 0. This can be checked using the `peaksCount` method, that returns the number of peaks (including 0 intensity peaks) in a spectrum. To effectively remove 0 intensity peaks from spectra, and reduce the size of the data set, one can use the `clean` method. The effect of the `removePeaks` and `clean` methods are illustrated on figure 7 on page 19.

```
> ## number of peaks
```

```
> peaksCount(itraqdata[["X55"]])
```

```
[1] 1726
```

```
> peaksCount(experiment[["X55"]])
```

```
[1] 1726
```

```
> experiment <- clean(experiment, verbose = FALSE)
```

```
> peaksCount(experiment[["X55"]])
```

```
[1] 442
```

Figure 7: This figure illustrated the effect of the `removePeaks` and `clean` methods. The left-most spectrum displays two peaks, of max height 3 and 7 respectively. The middle spectrum shows the result of calling `removePeaks` with argument $\tau=3$, which sets all data points of the first peak, whose maximum height is smaller or equal to τ to 0. The second peak is unaffected. Calling `clean` after `removePeaks` effectively deletes successive 0 intensities from the spectrum, as shown on the right plot.

6.2 Focusing on specific MZ values

Another useful manipulation method is `trimMz`, that takes as parameters and `MSnExp` (or a `Spectrum`) and a numeric `mzlim`. MZ values smaller than `min(mzlim)` or greater than `max(mzlim)` are discarded. This method is particularly useful when one wants to concentrate on a specific MZ range, as for reporter ions quantification, and generally results in substantial reduction of data size. Compare the size of the full trimmed experiment to the original 1.76 Mb.

```
> range(mz(itraqdata[["X55"]]))  
  
[1] 100.0 977.7  
  
> experiment <- trimMz(experiment, mzlim = c(112, 120))  
> range(mz(experiment[["X55"]]))  
  
[1] 113.1 117.1  
  
> experiment

As can be seen above, all processing performed on the experiment is recorded and displayed as integral part of the experiment object.

7 MS² isobaric tagging quantitation

7.1 Reporter ions quantitation

Quantitation is performed on fixed peaks in the spectra, that are specified with an **ReporterIons** object. A specific peak is defined by its expected **mz** value and is searched for within **mz ± width**. If no data is found, **NA** is returned.

```

> mz(iTRAQ4)

[1] 114.1 115.1 116.1 117.1

> width(iTRAQ4)

[1] 0.05

```

The **quantify** method takes the following parameters: an **MSnExp** experiment, a character describing the quantification **method**, the **reporters** to be quantified and a **strict** logical defining whether data points ranging outside of **mz ± width** should be considered for quantitation. Additionally, a progress bar can be displaying when setting the **verbose** parameter to **TRUE**. Three quantification methods are implemented, as illustrated on figure 8: **trapezoidation** returns the area under the peak of interest, **max** returns the apex of the peak and **sum** returns the sum of all intensities of the peak. See **?quantify** for more details.

Figure 8: The different quantitation methods are illustrated above. Quantitation using `sum` sums all the data points in the peaks to produce, for this example, 7, whereas method `max` only uses the peak's maximum intensity, 3. Trapezoidation calculates the area under the peak taking the full width into account (using `strict=FALSE` gives 0.375) or only the width as defined by the reporter (using `strict=TRUE` gives 0.2).

The `quantify` method returns `MSnSet` objects, that extend the well-known `eSet` class defined in the `Biobase` package. `MSnSet` instances are very similar to `ExpressionSet` objects, except for the experiment meta-data that captures MIAPE specific information. The assay data is a matrix of dimensions $n \times m$, where m is the number of features/spectra originally in the `MSnExp` used as parameter in `quantify` and n is the number of reporter ions, that can be accessed with the `exprs` method. The meta data is directly inherited from the `MSnExp` instance.

```
> qnt <- quantify(experiment,
+                 method = "trap",
+                 reporters = iTRAQ4,
+                 strict = FALSE,
+                 parallel = FALSE,
+                 verbose = FALSE)
> qnt

X14	6448	6234.2	6902.9	6437.2

If no peak is detected for a reporter ion peak, the respective quantitation value is set to **NA**. In our case, there is 1 such case in row 41. We will remove the offending line using the **filterNA** method. The **pNA** argument defines the percentage of accepted missing values per feature. As we do not expect any missing peaks, we set it to be 0 (which is also the default value).

```
> table(is.na(qnt))

FALSE  TRUE
  219     1

> qnt <- filterNA(qnt, pNA = 0)
> sum(is.na(qnt))

[1] 0
```

The filtering criteria for **filterNA** can also be defined as a pattern of columns that can have missing values and columns that must not exhibit any. See **?filterNA** for details and examples.

The infrastructure around the **MSnSet** class allows flexible filtering using the **[** sub-setting operator. Below, we mimic the behaviour of **filterNA(, pNA = 0)** by calculating the row indices that should be removed, i.e. those that have at least one **NA** value and explicitly remove these rows. This method allows one to devise and easily apply any filtering strategy.

```
> whichRow <- which(is.na(qnt))%nrow(qnt)
> qnt <- qnt[-whichRow, ]
```

See also the **plotNA** method to obtain a graphical overview of the completeness of a data set.

7.2 Importing quantitation data

If quantitation data is already available as a spreadsheet, it can be imported, along with additional optional feature and sample (pheno) meta data, with the `readMSnSet` function. This function takes the respective text-based spreadsheet (comma- or tab-separated) file names as argument to create a valid `MSnSet` instance.

Note that the quantitation data of `MSnSet` objects can also be exported to a text-based spreadsheet file using the `write.exps` method.

`MSnbase` also supports the `mzTab` format⁶, a light-weight, tab-delimited file format for proteomics data. `mzTab` files can be read into R with `readMzTabData` to create and `MSnSet` instance. `MSnSet` objects can also be exported to `mzTab` with the `writeMzTabData` function.

See the `MSnbase-io` vignette for a general overview of `MSnbase`'s input/output capabilities.

7.3 Peak adjustments

Single peak adjustment In certain cases, peak intensities need to be adjusted as a result of peak interference. For example, the +1 peak of the phenylalanine (F, Phe) immonium ion (with m/z 120.03) interferes with the 121.1 TMT reporter ion. Below, we calculate the relative intensity of the +1 peaks compared to the main peak using the `Rdispo` package.

```
> library(Rdispo)
> ## Phenylalanine immonium ion
> Fim <- getMolecule("C8H10N")
> getMass(Fim)

[1] 120.1

> isotopes <- getIsotope(Fim)
> F1 <- isotopes[2, 2]
> F1

[1] 0.08573
```

If desired, one can thus specifically quantify the F immonium ion in the MS2 spectrum, estimate the intensity of the +1 ion (0.0857% of the F peak) and subtract this calculated value from the 121.1 TMT reporter intensity.

⁶<http://code.google.com/p/mztab/>

The above principle can also be generalised for a set of overlapping peaks, as described below.

Reporter ions purity correction Impurities in the reporter reagents can also bias the results and can be corrected when manufacturers provide correction coefficients. These generally come as percentages of each reporter ion that have masses differing by -2, -1, +1 and +2 Da from the nominal reporter ion mass due to isotopic variants. The `purityCorrect` method applies such correction to `MSnSet` instances. It also requires a square matrix as second argument, `impurities`, that defines the relative percentage of reporter in the quantified each peak. See `?purityCorrect` for more details.

```
> impurities <- matrix(c(0.929, 0.059, 0.002, 0.000,
+                        0.020, 0.923, 0.056, 0.001,
+                        0.000, 0.030, 0.924, 0.045,
+                        0.000, 0.001, 0.040, 0.923),
+                       nrow = 4)
> qnt.crct <- purityCorrect(qnt, impurities)
> head(exprs(qnt))
```

	iTRAQ4.114	iTRAQ4.115	iTRAQ4.116	iTRAQ4.117
X1	1348	2247.3	3927.7	7661.1
X10	740	799.4	712.6	940.7

X13	27508.0	29440.9	28390.5	28814.2
X14	6809.8	6090.8	6799.5	6636.1

The `makeImpuritiesMatrix` can be used to create impurity matrices. It opens a rudimentary spreadsheet that can be directly edited.

7.4 Normalisation

A `MSnSet` object is meant to be compatible with further downstream packages for data normalisation and statistical analysis. There is also a `normalise` (also available as `normalize`) method for expression sets. The method takes an instance of class `MSnSet` as first argument, and a character to describe the method to be used:

quantiles Applies quantile normalisation (Bolstad et al., 2003) as implemented in the `normalize.quantiles` function of the `preprocessCore` package.

quantiles.robust Applies robust quantile normalisation (Bolstad et al., 2003) as implemented in the `normalize.quantiles.robust` function of the `preprocessCore` package.

vsn Applies variance stabilisation normalization (Huber et al., 2002) as implemented in the `vsn2` function of the `vsn` package.

max Each feature's reporter intensity is divided by the maximum of the reporter ions intensities.

sum Each feature's reporter intensity is divided by the sum of the reporter ions intensities.

See `?normalise` for more methods. A `scale` method for `MSnSet` instances, that relies on the `base::scale` function.

```
> qnt.max <- normalise(qnt, "max")
> qnt.sum <- normalise(qnt, "sum")
> qnt.quant <- normalise(qnt, "quantiles")
> qnt.qrob <- normalise(qnt, "quantiles.robust")
> qnt.vsn <- normalise(qnt, "vsn")
```

The effect of these are illustrated on figure 9 and figure 10 reproduces figure 3 of Karp et al. (2010) that described the application of vsn on iTRAQ reporter data.

Note that it is also possible to normalise individual spectra or whole `MSnExp` experiments with the `normalise` method using the `max` method. This will rescale all peaks between 0 and 1. To visualise the relative reporter peaks, one should first trim the spectra using method `trimMz` as illustrated in section 6, then normalise the `MSnExp` with `normalise` using `method="max"` as illustrated above and plot the data using `plot` (figure 11).

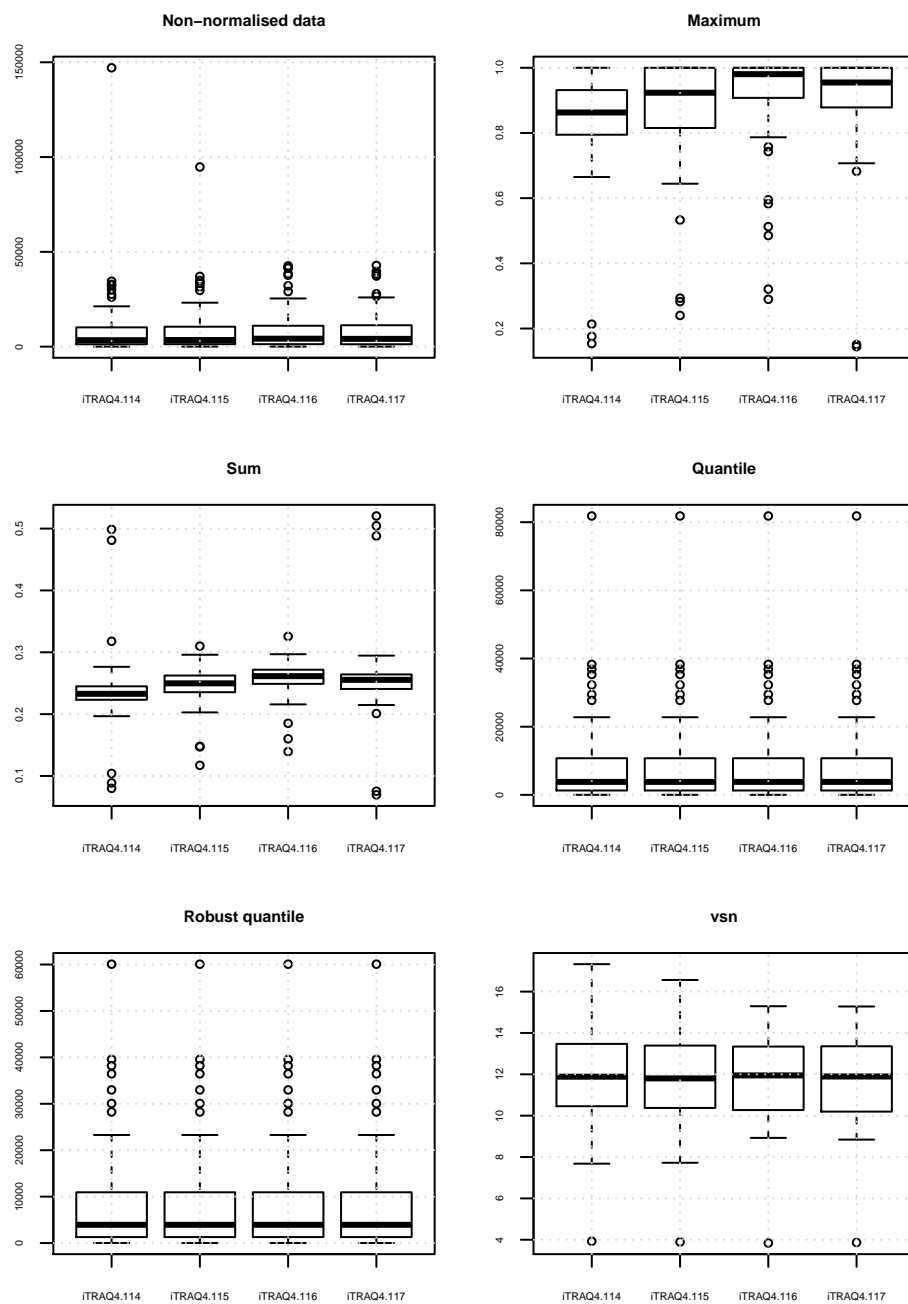

Figure 9: Comparison of the normalisation MSnSet methods. Note that vsn also glog-transforms the intensities.

Figure 10: CV versus signal intensity comparison for log2 and vsn transformed data. Lines indicate running CV medians.

Additional dedicated normalisation method are available for MS² label-free quantitation, as described in section 9 and in the `quantify` documentation.

8 Feature aggregation

The above quantitation and normalisation has been performed on quantitative data obtained from individual spectra. However, the biological unit of interest is not the spectrum but the peptide or the protein. As such, it is important to be able to summarise features that belong to a same group, i.e. spectra from one peptide, peptides that originate from one protein, or directly combine all spectra that have been uniquely associated to one protein.

`MSnbase` provides one function, `combineFeatures`, that allows to aggregate features stored in an `MSnSet` using build-in or user defined summary function and return a new `MSnSet` instance. The three main arguments are described below. Additional details can be found in the method documentation.

`combineFeatures`'s first argument, `object`, is an instance of class `MSnSet`, as has been created in the section 7.1 for instance. The second argument, `groupBy`, is a `factor` than has as many elements as there are features in the `MSnSet` `object` argument. The features corresponding to the `groupBy` levels

Figure 11: Experiment-wide normalised MS2 spectra. The y-axes of the individual spectra is now rescaled between 0 and 1 (highest peak), as opposed to figure 2.

will be aggregated so that the resulting `MSnSet` output will have `length(levels(groupBy))` features. Here, we will combine individual MS2 spectra based on the protein they originate from. As shown below, this will result in 40 new aggregated features.

```
> gb <- fData(qnt)$ProteinAccession
> table(gb)

gb
      BSA ECA0172 ECA0435 ECA0452 ECA0469 ECA0621 ECA0631 ECA0691
      3       1       2       1       2       1       1       1
ECA0871 ECA0978 ECA1032 ECA1093 ECA1104 ECA1294 ECA1362 ECA1363
      1       1       1       1       1       1       1       1
ECA1364 ECA1422 ECA1443 ECA2186 ECA2391 ECA2421 ECA2831 ECA3082
      1       1       1       1       1       1       1       1
ECA3175 ECA3349 ECA3356 ECA3377 ECA3566 ECA3882 ECA3929 ECA3969
      1       2       1       1       2       1       1       1
ECA4013 ECA4026 ECA4030 ECA4037 ECA4512 ECA4513 ECA4514      ENO
      1       2       1       1       1       1       6       3

> length(unique(gb))

[1] 40
```

The third argument, `fun`, defined how to combine the features. Predefined functions are readily available and can be specified as strings (`fun="mean"`, `fun="median"`, `fun="sum"`, `fun="weighted.mean"` or `fun="medianpolish"` to compute respectively the mean, media, sum, weighted mean or median polish of the features to be aggregated). Alternatively, is is possible to supply user defined functions with `fun=function(x) { ... }`. We will use the `median` here.

```
> qnt2 <- combineFeatures(qnt, groupBy = gb, fun = "median")

Combined 54 features into 40 using median

> qnt2

9 Label-free MS² quantitation

9.1 Peptide counting

Note that if samples are not multiplexed, label-free MS² quantitation by spectral counting is possible using MSnbase. Once individual spectra have been assigned to peptides and proteins (see section 4), it becomes straightforward to estimate protein quantities using the simple peptide counting method, as illustrated in section 8.

```

> sc <- quantify(msexp, method = "count")
> ## lets modify out data for demonstration purposes
> fData(sc)$accession[1] <- fData(sc)$accession[2]
> fData(sc)$accession

[1] "ECA1028" "ECA1028" "ECA0510"

```

```
> sc <- combineFeatures(sc, groupBy = fData(sc)$accession, fun = "sum")

Combined 3 features into 2 using sum

> exprs(sc)

      1
ECA0510 1
ECA1028 2
```

Such count data could then be further analysed using dedicated count methods (originally developed for high-throughput sequencing) and directly available for `MSnSet` instances in the `msmsTests` Bioconductor package.

9.2 Spectral counting and intensity methods

The spectral abundance factor (SAF) and the normalised form (NSAF) (Paoletti et al., 2006) as well as the spectral index (SI) and other normalised variations (SI_{GI} and SI_N) (Griffin et al., 2010) are also available. Below, we illustrate how to apply the normalised SI_N to the experiment containing identification data produced in section 4.

The spectra that did not match any peptide have already been removed with the `removeNoId` method. As can be seen in the following code chunk, the first spectrum could not be matched to any single protein. Non-identified spectra and those matching multiple proteins are removed automatically prior to any label-free quantitation. One can also remove peptide that do not match uniquely to proteins (as defined by the `npsm` feature variable column) with the `removeMultipleAssignment` method.

```
> fData(msexp)[, c("accession", "npsm")]

      accession npsm
X1.1 ECA0984;ECA3829    2
X2.1      ECA1028     1
X5.1      ECA0510     1
```

Note that the label-free methods implicitly apply feature aggregation (section 8) and normalise (section 7.4) the quantitation values based on the total sample intensity and/or the protein lengths (see Paoletti et al. (2006) and Griffin et al. (2010) for details).

Let's now proceed with the quantitation using the `quantify`, as in section 7.1, this time however specifying the method of interest, "SIn" (the `reporters`

argument can of course be ignored here). The required peptide-protein mapping and protein lengths are extracted automatically from the feature meta-data using the default `accession` and `length` feature variables.

```
> siquant <- quantify(msexp, method = "SIn")

Combined 2 features into 2 using sum

> processData(siquant)

- - - Processing information - - -
Data loaded: Tue Apr 22 03:06:39 2014
Filtered 2 unidentified peptides out: Tue Apr 22 03:06:41 2014
Removed 1 features assigned to multiple proteins: Tue Apr 22 03:06:53 2014
Combined 2 features into 2 using sum: Tue Apr 22 03:06:53 2014
Quantification by SIn: Tue Apr 22 03:06:53 2014
MSnbase version: 1.12.1

> exprs(siquant)

              1
ECA0510 0.003589
ECA1028 0.001470
```

Other label-free methods can be applied by specifying the appropriate `method` argument. See `?quantify` for more details.

10 Quantitative assessment of incomplete dissociation

Quantitation using isobaric reporter tags assumes complete dissociation between the reporter group (red on figure 12), balance group (blue) and peptide (the peptide reactive group is drawn in green). However, incomplete dissociation does occur and results in an isobaric tag (i.e reporter and balance groups) specific peaks.

MSnbase provides, among others, a `ReporterIons` object for iTRAQ 4-plex that includes the 145 peaks, called `iTRAQ5`. This can then be used to quantify the experiment as show in section 7.1 to estimate incomplete dissociation for each spectrum.

Figure 12: iTRAQ 4-plex isobaric tags reagent consist of three parts: (1) a charged reporter group (MZ of 114, 115, 116 and 117) that is unique to each of the four reagents (red), (2) an uncharged mass balance group (28-31 Da) (blue) and (3) a peptide reactive group (NHS ester) that binds to the peptide. In case of incomplete dissociation, the reporter and balance groups produce a specific peaks at MZ 145.

```
> iTRAQ5

X14	6448	6234.2	6902.9	6437.2	427.7

Figure 13 compares these intensities for the whole experiment.

Figure 13: Boxplot and scatterplot comparing intensities of the 4 reporter ions (or their sum, on the right) and the incomplete dissociation specific peak.

11 Combining MSnSet instances

Combining mass spectrometry runs can be done in two different ways depending on the nature of these runs. If the runs represent repeated measures of identical samples, for instance multiple fractions, the data has to be combined along the row of the quantitation matrix: all the features (along the rows) represent measurements of the same set of samples (along the columns). In this situation, described in section 11.1, two experiments of dimensions n_1 (rows) by m (columns) and n_2 by m will produce a new experiment of dimensions $n_1 + n_2$ by m .

When however, different sets of samples have been analysed in different mass spectrometry runs, the data has to be combined along the columns of the quantitation matrix: some features will be shared across experiments and should thus be aligned on a same row in the new data set, whereas unique features to one experiment should be set as missing in the other one. In this situation, described in section 11.2, two experiments of dimensions n_1 by m_1 and n_2 by m_2 will produce a new experiment of dimensions $unique_{n_1} + unique_{n_2} + shared_{n_1, n_2}$ by $m_1 + m_2$. The two first terms of the first dimension will be complemented by NA values.

Default `MSnSet` feature names (`X1`, `X2`, ...) and sample names (`iTRAQ4.114`, `iTRAQ4.115`, `iTRAQ4.116`, ...) are not informative. The features and samples of these anonymous quantitative data-sets should be updated before being combined, to guide how to meaningfully merge them.

11.1 Combining identical samples

To simulate this situation, let us use quantitation data from the `itraqdata` object that is provided with the package as experiment 1 and the data from the `rawdata` `MSnExp` instance created at the very beginning of this document. Both experiments share the *same* default iTRAQ 4-plex reporter names as default sample names, and will thus automatically be combined along rows.

```
> exp1 <- quantify(itraqdata, reporters = iTRAQ4,
+                  parallel = FALSE, verbose = FALSE)
> sampleNames(exp1)

[1] "iTRAQ4.114" "iTRAQ4.115" "iTRAQ4.116" "iTRAQ4.117"

> exp2 <- quantify(rawdata, reporters = iTRAQ4,
+                  parallel = FALSE, verbose = FALSE)
> sampleNames(exp2)

[1] "iTRAQ4.114" "iTRAQ4.115" "iTRAQ4.116" "iTRAQ4.117"
```

It is important to note that the features of these independent experiments share the same default anonymous names: X1, X2, X3, ..., that however represent quantitation of distinct physical analytes. If the experiments were to be combined as is, it would result in an error because data points for the same *feature* name (say X1) and the same *sample name* (say iTRAQ4.114) have different values. We thus first update the feature names to explicitate that they originate from different experiments and represent quantitation from different spectra using the convenience function `updateFeatureNames`. Note that updating the names of one experiment would suffice here.

```
> head(featureNames(exp1))

[1] "X1" "X10" "X11" "X12" "X13" "X14"

> exp1 <- updateFeatureNames(exp1)
> head(featureNames(exp1))

[1] "X1.exp1" "X10.exp1" "X11.exp1" "X12.exp1" "X13.exp1"
[6] "X14.exp1"

> head(featureNames(exp2))

[1] "X1.1" "X2.1" "X3.1" "X4.1" "X5.1"
```

```
> exp2 <- updateFeatureNames(exp2)
> head(featureNames(exp2))

[1] "X1.1.exp2" "X2.1.exp2" "X3.1.exp2" "X4.1.exp2" "X5.1.exp2"
```

The two experiments now share the same sample names and have different feature names and will be combined along the row. Note that all meta-data is correctly combined along the quantitation values.

```
> exp12 <- combine(exp1, exp2)

11.2 Combine different samples

Lets now create two `MSnSets` from the same raw data to simulate two different independent experiments that share some features. As done previously (see section 8), we combine the spectra based on the proteins they have been identified to belong to. Features can thus naturally be named using protein accession numbers. Alternatively, if peptide sequences would have been used as grouping factor in `combineFeatures`, then these would be good feature name candidates.

```
> set.seed(1)
> i <- sample(length(itraqdata), 35)
> j <- sample(length(itraqdata), 35)
> exp1 <- quantify(itraqdata[i], reporters = iTRAQ4,
```

```

+               parallel = FALSE, verbose = FALSE)
> exp2 <- quantify(itraqdata[j], reporters = iTRAQ4,
+               parallel = FALSE, verbose = FALSE)
> exp1 <- droplevels(exp1)
> exp2 <- droplevels(exp2)
> table(featureNames(exp1) %in% featureNames(exp2))

FALSE  TRUE
    12    23

> exp1 <- combineFeatures(exp1,
+               groupBy = fData(exp1)$ProteinAccession)

Combined 35 features into 27 using mean

> exp2 <- combineFeatures(exp2,
+               groupBy = fData(exp2)$ProteinAccession)

Combined 35 features into 27 using mean

> head(featureNames(exp1))

[1] "BSA"      "ECA0435" "ECA0469" "ECA0621" "ECA0631" "ECA0978"

> head(featureNames(exp2))

[1] "BSA"      "ECA0172" "ECA0435" "ECA0452" "ECA0469" "ECA0621"

```

The `droplevels` drops the unused `featureData` levels. This is required to avoid passing absent levels as `groupBy` in `combineFeatures`. Alternatively, one could also use `factor(fData(exp1)$ProteinAccession)` as `groupBy` argument.

The feature names are updated automatically by `combineFeatures`, using the `groupBy` argument. Proper feature names, reflecting the nature of the features (spectra, peptides or proteins) is critical when multiple experiments are to be combined, as this is done using common features as defined by their names (see below).

Sample names should also be updated to replace anonymous reporter names with relevant identifiers; the individual reporter data is stored in the `phenoData` and is not lost. A convenience function `updateSampleNames` is provided to append the `MSnSet`'s variable name to the already defined names, although in

general, biologically relevant identifiers are preferred.

```
> sampleNames(exp1)

[1] "iTRAQ4.114" "iTRAQ4.115" "iTRAQ4.116" "iTRAQ4.117"

> exp1 <- updateSampleNames(exp1)
> sampleNames(exp1)

[1] "iTRAQ4.114.exp1" "iTRAQ4.115.exp1" "iTRAQ4.116.exp1"
[4] "iTRAQ4.117.exp1"

> sampleNames(exp1) <- c("Ctrl1", "Cond1", "Ctrl2", "Cond2")
> sampleNames(exp2) <- c("Ctrl3", "Cond3", "Ctrl4", "Cond4")
```

At this stage, it is not yet possible to combine the two experiments, because their feature data is not compatible yet; they share the same feature variable labels, i.e. the feature data column names (spectrum, ProteinAccession, ProteinDescription, ...), but the part of the content is different because the original data was (in particular all the spectrum centric data: identical peptides in different runs will have different retention times, precursor intensities, ...). Feature data with identical labels (columns in the data frame) and names (row in the data frame) are expected to have the same data and produce an error if not conform.

```
> stopifnot(all(fvarLabels(exp1) == fvarLabels(exp2)))
> fData(exp1)["BSA", 1:4]

      spectrum ProteinAccession ProteinDescription PeptideSequence
BSA          1              BSA bovine serum albumin            NYQEAK

> fData(exp2)["BSA", 1:4]

      spectrum ProteinAccession ProteinDescription PeptideSequence
BSA          52              BSA bovine serum albumin            QTALVELLK
```

Instead of removing these identical feature data columns, one can use a second convenience function, `updateFvarLabels`, to update feature labels based on the experiments variable name and maintain all the metadata.

```

> exp1 <- updateFvarLabels(exp1)
> exp2 <- updateFvarLabels(exp2)
> head(fvarLabels(exp1))

[1] "spectrum.exp1"          "ProteinAccession.exp1"
[3] "ProteinDescription.exp1" "PeptideSequence.exp1"
[5] "file.exp1"              "retention.time.exp1"

> head(fvarLabels(exp2))

[1] "spectrum.exp2"          "ProteinAccession.exp2"
[3] "ProteinDescription.exp2" "PeptideSequence.exp2"
[5] "file.exp2"              "retention.time.exp2"

```

It is now possible to combine **exp1** and **exp2**, including all the meta-data, with the **combine** method. The new experiment will contain the union of the feature names of the individual experiments with missing values inserted appropriately.

```

> exp12 <- combine(exp1, exp2)
> dim(exp12)

[1] 35  8

> pData(exp12)

Combined [35,8] and [27,4] MSnSets Tue Apr 22 03:07:06 2014
MSnbase version: 1.1.22

```

In summary, when experiments with different samples need to be combined (along the columns), one needs to (1) clarify the sample names using `updateSampleNames` or better manually, for biological relevance and (2) update the feature data variable labels with `updateFvarLabels`. The individual experiments (there can be more than 2) can then easily be combined with the `combine` method while retaining the meta-data.

If runs for the same sample (different fractions for example) need to be combined, one needs to (1) differentiate the feature provenance with `updateFeatureNames` prior to use `combine`.

12 MS^E data processing

MSnbase can also be used for MS^E data independent acquisition from Waters instrument. The MS^E pipeline depends on the Bioconductor `synapter` package (Bond et al., 2013) that produces `MSnSet` instances for individual acquisitions. The MSnbase infrastructure can subsequently be used to further combine experiments, as shown in section 11.2 and apply *top3* quantitation using the `topN` method.
