1 Introduction

interactiveDisplay makes use of Bioconductor visualization packages, the Shiny [8] web framework, the D3.js visualization JavaScript library, and other libraries to produce various web applications built around Bioconductor objects.

Four popular Bioconductor data objects are currently supported: *GRanges*, *GRangesList*, *ExpressionSet* and *SummarizedExperiment*. In addition, the second April 2014 release version now includes a method for data frames and is imported by the AnnotationHub [1] package.

This vignette will provide some background and guidance on the use of the current supported methods.

2 Installation

The webpage for the release version of interactiveDisplay is available at:

<http://bioconductor.org/packages/release/bioc/html/interactiveDisplay.html>

And the development version is available at:

<http://bioconductor.org/packages/devel/bioc/html/interactiveDisplay.html>

It can also be installed within the R console using `biocLite()`.

```
source("http://bioconductor.org/biocLite.R")
biocLite("interactiveDisplay")
```

`interactiveDisplay` is actively maintained and it may be desirable to use the developer branch of the package. If the user is willing to install development versions of Bioconductor packages, this can be accomplished by toggling the setting with `useDevel()` and reinstalling packages with `biocLite()`. The development branch is actively changed, so users should expect to encounter errors. Generally, development and release versions of packages should not be mixed.

```
source("http://bioconductor.org/biocLite.R")
useDevel(TRUE)
biocLite("interactiveDisplay")
```

Because `interactiveDisplay` depends on many different R packages, some of which are used in only one individual method, many dependencies are suggested and will only be required when a method is run for the first time. This helps with load time when other packages (currently `AnnotationHub`) import methods from `interactiveDisplay`. If a required package is missing when a method is run, a message with instructions on obtaining it will be output in the R console.

3 Support

- Send me an email directly at balc0022@umn.edu
- Search, subscribe or contact the `bioconductor` or `bioc-devel` mailing lists at <http://www.bioconductor.org/help/mailling-list/>

5 Bioconductor Object Methods

5.1 GRanges and GRangesList

5.1.1 Object Background - GRanges

The *GRanges* object is a standardized container for genomic location data used in many Bioconductor packages. It is built on S4 classes from the the infrastructure package IRanges.

First, load the libraries needed for the examples in this document and load the example *GRanges* data provided with the interactiveDisplay package.

```
options(width=80)
options(continue=" ")
suppressMessages(library(ggplot2))
suppressMessages(library(interactiveDisplay))
suppressMessages(library(Biobase))
```

```
data(mmgr)
```

```
mmgr
```

```
## Loading required package: GenomicRanges
## Loading required package: S4Vectors
## Loading required package: stats4
## Loading required package: IRanges
## Loading required package: GenomeInfoDb
```

```
## GRanges object with 1000 ranges and 2 metadata columns:
```

```

##     [1000] ENSMUST00000172093
##      -----
##      seqinfo: 9 sequences from an unspecified genome
```

Each row in the *GRanges* object represents an individual range using the *IRanges* Bioconductor object to store the first and last position on the sequence. The chromosome and strand designation are both stored using run-length encoding (rle) for efficiency. The sequence lengths of are also stored in the *GRanges*. Any columns to the right of the pipe symbols in the object are metadata columns. Practically any R data object can be stored in the metadata, it is left up to the user and is often dependent on the experimental context of the data that is being conformed to the *GRanges* standard. For instance, to represent interactions between ranges, it is possible to store a *GRanges* object within another *GRanges* object's metadata. In the example here, transcript information has been inserted in the metadata.

5.1.2 Object Background - *GRangesList*

The *GRangesList* class is a container for storing a list of *GRanges* objects, the class is produced with the function `GenomicRangesList()`.

```
grl <- GenomicRangesList(list(mmgr,mmgr))
```

GRangesList objects are useful for compound objects, an example given in the documentation being spliced transcripts that are made up of exons [4]

```

```

5.1.3 Method

The `display()` function in `interactiveDisplay` will start a Shiny web application tailored to the particular supported object passed as an argument. Both the *GRanges* and *GRangesList* data objects can be visualized as follows:

```
display(mmgr)
```

```
display(mmgrl)
```

It is also important to note, the *GRanges* and *GRangesList* methods are designed to send a subset of the submitted object back to the console as a result when the GUI application is exited. If the user wants to store this new object, simply assign it as illustrated in the following examples.

```
new_mmgr <- display(mmgr)
```

```
new_mmgrl <- display(mmgrl)
```

While simple in concept, data cleaning and wrangling are universal to any workflow, so this is a reasonable first implementation of Shiny's capability of returning results back to R.

5.1.4 UI

Unlike other visualization packages that are run in the console and lend themselves to walkthroughs and examples using the `knitr` package, `interactiveDisplay`'s reliance on Shiny moves many of its functional components outside of the R console. This section will be a walkthrough of the user interface controls and features of the applications produced from the *GRanges* and *GRangesList* methods. Besides a couple small exceptions, these two methods are functionally similar and their descriptions have been consolidated together.

Figure 1: GRange, Chromosome drop-down menus

These dropdown UI elements are used to select a particular *GRanges* and ranges associated with a chosen chromosome (The *GRanges* dropdown is not present in the *GRangesList* method). These ranges will be shown in the **Interactive Plot** and the subsetting operations in the other UI elements will apply to these active ranges.

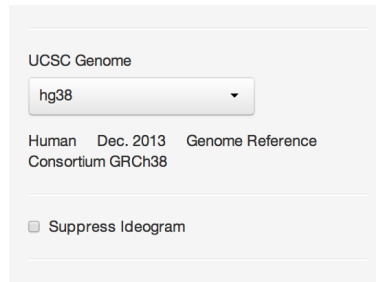

Figure 2: UCSC Genome drop-down, Suppress Ideogram checkbox

The **UCSC Genome** dropdown gives the user choices for the ideogram image shown above the trackplots. This selection is entirely determined by the user and the particular data in the *GRange*/*GRangesList* may not correspond to any of the available choices. This feature also depends on access to remote UCSC servers. Because the correct ideogram may not be available, it can be suppressed via the **Suppress Ideogram** checkbox element.

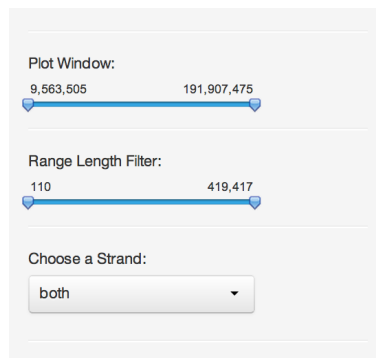

Figure 3: Plot Window Range slider, Length Filter slider, Choose a Strand drop-down

The **Plot Window** and **Range Length Filter** sliders and **Choose a Strand** dropdown provide the user with options for subsetting the original data to only the current ranges in view. The **Plot Window** is reflected by the highlighted region on the ideogram in addition to the trackplot below it. The **Range Length Filter** can be used to filter ranges shown by their respective lengths. The **Choose a Strand** dropdown gives the user a choice of displaying ranges located on positive, negative, or both strands.

Figure 4: Deposit Ranges in View button, Clear Deposit button, Save to Console button

Besides subsetting which ranges are in the current view, the current subset of ranges can be saved. This is a two step process. Ranges of interest are first deposited, allowing the user to select different chromosomes/*GRanges* to manipulate and add to the list of deposited selections. Once the user is ready to return the data back to the console, **Save to Console** stops the Shiny session and returns the subsetting *GRanges* or *GRangesList* object. **Clear Deposit** resets all selections. The usefulness of this feature is left to the user's individual needs and is also very dependent on the data submitted. Upon inspection, ranges of interest may fall on the same chromosome or chromosome region, share specific metadata tags, or individual lengths. The Shiny UI offers an alternative to filtering away unwanted ranges iteratively in the console with multiple subsetting commands (and repeatedly printing output for validation), while providing instant visual feedback.

5.1.5 Plots

Figure 5: Static Circle Layout

The **Static Circle Layout** is a ggbio [11] based plot is provided for overview purposes and is not intended to represent the user's current subsetting operations. It provides the user with a broad summary of the data they submitted in its unaltered form.

Figure 6: Interactive Plot

The **Interactive Plot** is the main view for these two methods. Trackplots are drawn with the Bioconductor package Gviz [3].

Figure 9: Deposited Selections

This table view doesn't show individual ranges, instead it gives a summary of selected ranges that have been locked in with the **Deposit Ranges in View** button. Here the user can keep track of sets of ranges of interest that can be sent back to the console when the application is closed.

5.1.6 Metadata Tabset

Select tx_name
☒ ENSMUST00000033088
☒ ENSMUST00000038824
☒ ENSMUST00000084338
☐ ENSMUST00000109152
☒ ENSMUST00000121813
☒ ENSMUST00000144433
☐ ENSMUST00000147148
☐ ENSMUST00000148260
☐ ENSMUST00000167068
☒ ENSMUST00000172093

Figure 10: Dynamically Created Metadata Tabs

The lower tabset consists of individual tabs that are dynamically produced based on the metadata contents of the object submitted. Each tab has a list of checkboxes that allow the user to subset the selection based on the metadata. The subsetting is applied across all deposited selections. The usefulness of this panel really depends on the content of the object submitted. Objects containing no metadata columns obviously have no use for this UI, but metadata rich objects with categorical, biologically relevant labels can potentially be subset quickly according to them.

5.2 ExpressionSet

5.2.1 Object Background

The *ExpressionSet* class is a standardized container for gene expression data, specifically from a microarray.

```
data(expr)
expr

## ExpressionSet (storageMode: lockedEnvironment)
## assayData: 500 features, 26 samples
##   element names: exprs, se.exprs
## protocolData: none
## phenoData
##   sampleNames: A B ... Z (26 total)
##   varLabels: sex type score
##   varMetadata: labelDescription
## featureData: none
## experimentData: use 'experimentData(object)'
## Annotation: hgu95av2
```

We can view the expression values with the `exprs()` function.

```
exprs(expr)[1:10,1:7]
```

The structure of the *ExpressionSet* object [4]:

- expression data (assayData)
- sample metadata (phenoData)
- annotations and instrument metadata (featureData, annotation)
- sample protocol (protocolData)
- experimental design (experimentData)

5.2.2 Method

```
display(expr)
```

5.2.3 UI

The method for *ExpressionSet* has the most features of any of the current objects handled by interactiveDisplay. The main panel consists of three tabs that visualize the data as a heatmap, network and dendrogram. Gene ontology summaries of probes or selected probe clusters are available in tables in the lower tabset of the main panel.

Experiment Info	
name	Pierre Fermat
lab	Francis Galton Lab
contact	pfermat@lab.not.exist
title	Smoking-Cancer Experiment
url	www.lab.not.exist

Figure 11: Experiment Info

The Experiment Info table at the top of the sidebar is entirely dependent on whether the *ExpressionSet* object submitted has these fields filled out.

Figure 12: Suppress Heatmap checkbox, Transpose Heatmap checkbox

Depending on whether the parameter `sflag=FALSE` is passed to the `display()` method and the selected dimensions of the *ExpressionSet*, replotting the heatmap can introduce delays. Using the checkbox to suppress the heatmap plotting can circumvent this. Also, depending on the relative dimensions of probes/samples, transposing the plot can make better use of the space available.

Figure 13: Network/Dendrogram View dropdown

This UI element simply toggles between displaying plots that represent distances/clustering across probes or samples.

Figure 14: Group Wide GO Summary UI

This set of UI elements can be used to provide a gene ontology summary of a chosen cluster of probes in the network view. Simply mouseover a node within a cluster of interest and the cluster number will pop-up. Input that cluster number into the input field and hit the **View/Update GO Summary** button. This can take 10-30 seconds, which is why this is not automatically reactive. Adjusting the Minimum probe population for GO term allows the user to explore general or specific top ranking terms. The summary table is located in the second tab of the lower tabset.

Figure 15: Individual Probe GO Summary dropdown

This drop-down contains options from the current subset of probes being visualized. Selecting a probe refreshes the first tab of the lower tabset with a GO summary for that probe, as well as associated gene names and Entrez IDs. When toggled to probe view, clicking on a probe node in the network view also refreshes this selection and may be more convenient.

A web form titled 'Subset UI'. It contains four controls: a dropdown menu labeled 'Show Top or Bottom Ranked,' with 'top' selected; a dropdown menu labeled 'Based On:' with 'variance' selected; a text input field labeled 'Number of Probes to Display' with the value '50'; and a text input field labeled 'Number of Samples to Display' with the value '26'.

Figure 16: Subset UI

This UI set is used for subsetting the submitted *ExpressionSet* object. The initial values are set to the maximum number of samples and to a very conservative 20 probes. The user is free to expand out to the full dimensions.

A slider control titled 'Tweak Axis Label Font Size'. The slider has a range from -1 to 1, with major tick marks at -1, 0.7, and 1. A blue diamond handle is positioned at 0.7.

Figure 17: Tweak Axis Label Font Size slider

Depending on the dimensions of the *ExpressionSet* object submitted/subset, it may be necessary to adjust label sizes to prevent label overlapping or illegibly small text.

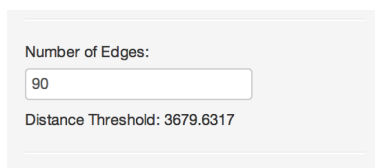

A web form titled 'Edge/Distance UI'. It contains two controls: a text input field labeled 'Number of Edges:' with the value '90'; and a text label 'Distance Threshold: 3679.6317'.

Figure 18: Edge/Distance UI

This UI element is used in the network view, allowing the user to determine the number of edges and the distance threshold represented in the graph.

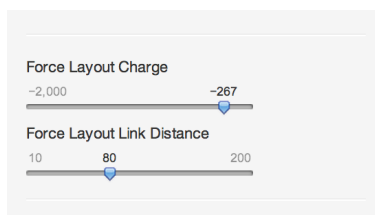

Two slider controls. The first is titled 'Force Layout Charge' and has a range from -2,000 to -267, with a blue diamond handle at -267. The second is titled 'Force Layout Link Distance' and has a range from 10 to 200, with a blue diamond handle at 80.

Figure 19: Force Layout sliders

This is a cosmetic control for the force directed graph, which allows the user to adjust how nodes spread themselves out and the length of their edges.

A screenshot of a web-based user interface for clustering. It contains three controls: a text input field labeled 'Number of Clusters:' with the value '9', a dropdown menu labeled 'Hierarchical Clustering Method' with 'ward' selected, and another dropdown menu labeled 'Distance/Similarity Method' with 'euclidean' selected.

Figure 20: Clustering UI

These controls set the parameters for the distance and hierarchical clustering methods used. Only base R methods are currently implemented but more may be included in future releases as well as possible option of allowing the user to manually provide their own via a textbox element.

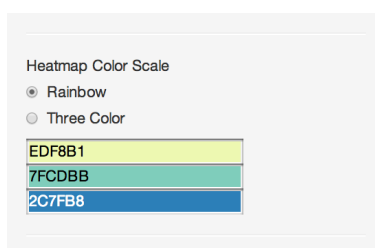

A screenshot of a web-based color picker interface. It has a section titled 'Heatmap Color Scale' with two radio buttons: 'Rainbow' (selected) and 'Three Color'. Below the radio buttons is a vertical color bar with three distinct color segments: yellow at the top, green in the middle, and blue at the bottom. Each segment is labeled with a hex color code: 'EDF8B1' for the yellow segment, '7FCDBB' for the green segment, and '2C7FB8' for the blue segment.

Figure 21: Color Picker UI

These elements affect the coloration of the heatmap. The color picker for the tricolor scale is not provided by the Shiny framework. This uses an additional JavaScript library which will be discussed in a later section. This is not just a cosmetic option, different modes can better visualize different data and accommodate color blind users.

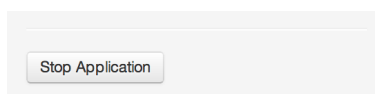

A screenshot of a web-based button labeled 'Stop Application'.

Figure 22: Stop Application button

This stops the application. The *ExpressionSet* method does not currently return any data back to the R console.

5.2.4 Plots

Figure 25: Network View - Probes

The **Network View** uses a D3.js based force directed graph to visualize distance/similarity between samples or probes based on user selected distance methods and threshold settings. Nodes in the graph are colored based on cluster settings. As stated previously, when the view is toggled to display probes, there is the added interface functionality of being to use the graph to conveniently gather GO information. When used in conjunction with the heatmap view, the network graph can quickly convey to the user which samples have similar profiles or which probes have similar expression across samples.

Figure 26: Dendrogram - Samples

Figure 27: Dendrogram - Probes

The decision to separate the dendrogram plots from the heatmap was a difficult one, paired heatmap/dendrogram plots quickly convey clustering groupings alongside the data that they were generated from. However, due to the forementioned design/layout constraints, dendrograms are placed in their own tab. This keeps the already complex UI as clean as possible with adequate space for all plots. To accommodate this decision some care was taken to keep some consistency between views. The clustering colors are consistent across the three views and the sample/probe order is the same between the heatmap and dendrogram views. This consistency helps the user quickly switch between tabs and stay oriented with the data they are examining.

5.2.5 GO Tabset

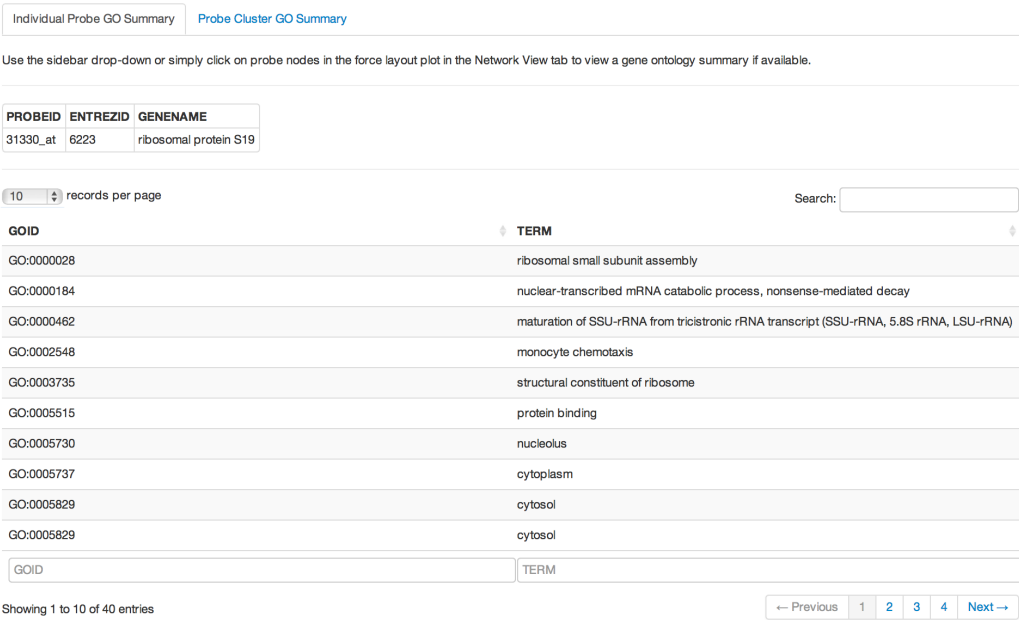

Figure 28: Individual Probe GO Summary

These summary tables provide Entrez ID and gene names for the selected probe and the top ranking results for GO descriptors. This table allows the user to manually choose and characterize probes that could be exhibiting differential expression in the submitted expressionSet.

Figure 29: Probe Cluster GO Summary

This tab provides a table of the results of the `hyperg()` function from the `GOstats` package [2]. Ranked in order of p-value, the results give a general GO summary across the group of selected probes. Much like the previous table, this provides an interactive tool for characterizing differentially expressed sets of probes.

5.3 SummarizedExperiment

5.3.1 Object Background

```
data(se)
se

## class: SummarizedExperiment
## dim: 14599 4
## exptData(0):
## assays(1): ''
## rownames(14599): FBgn0000003 FBgn0000008 ... FBgn0261574 FBgn0261575
## rowData metadata column names(8): id baseMean ... pval padj
## colnames(4): untreated3 untreated4 treated2 treated3
## colData names(1): Condition
```

The *SummarizedExperiment* class is similar to a dataframe where rows represent ranges (using *GRanges*/*GRangesList*) and columns represent samples (with sample data summarized as a dataframe). It can contain one or more assays. Ranges have read counts associated with them [4].

5.3.2 Method

```
display(se)
```

5.3.3 UI

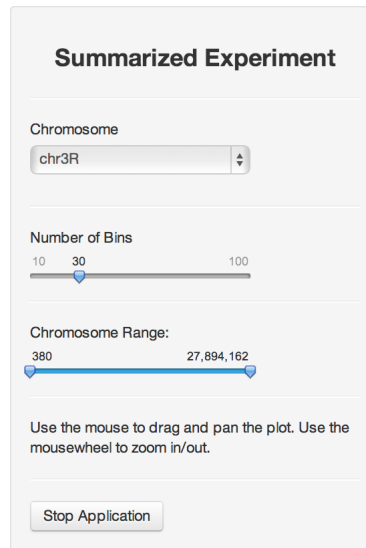

Figure 30: *SummarizedExperiment* UI

The UI for the *SummarizedExperiment* method is relatively simple. It is the best candidate of the existing methods for future development. The *SummarizedExperiment* class is widely used, data rich object and has a lot of potential for improvement.

5.3.4 Plot

Figure 31: Binned Mean Counts by Position

Currently the plot gives a simple depiction of expression score/counts across regions of the selected chromosome. However, this plot currently obfuscates the relative coverage of the ranges of interest. It will likely need to be replaced with a multiple track plot in future releases.

6 Additional Functions/Methods

6.1 Dataframe - `display()`

```
display(mtcars)
```

Similar to the `GRanges` and `GRangesList` methods, the dataframe method can send a subset of the submitted object back to the console and can be stored in a new variable.

```
new_mtcars <- display(mtcars)
```

Data Tables binding

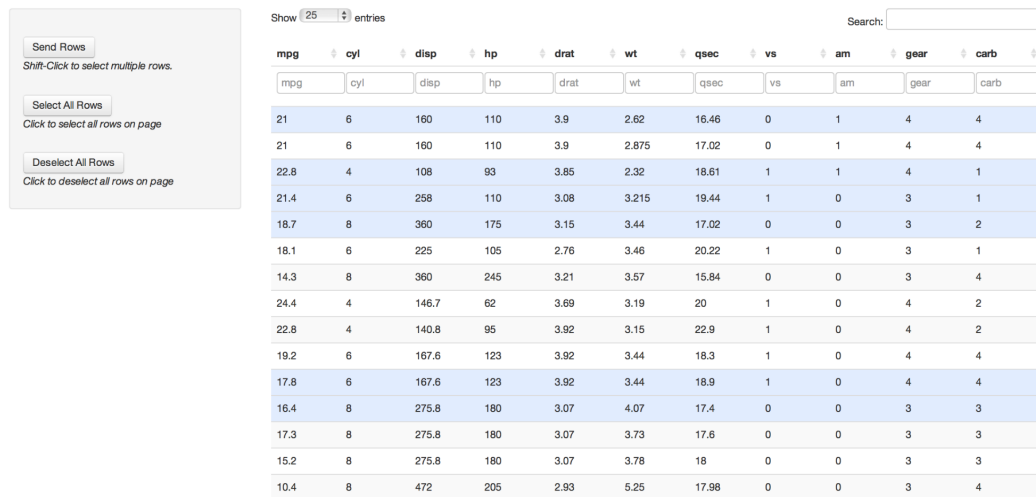

Figure 32: Dataframe Table

Despite the dataframe being a base R object and not exclusive to use with Bioconductor software, it's still useful to write methods for base R objects with genomic workflows in mind. The Bioconductor package AnnotationHub imports this dataframe method. This method makes use of Shiny's new advanced datatables with a slight modification to return selected rows back to the console.

6.2 Dataframe - simplenet()

```
simplenet(mtcars)
```

Figure 33: simplenet

Code to produce the force network tab from the *ExpressionSet* tab was recently converted to a stand-alone method for numeric dataframes in the developer branch of interactiveDisplay.

6.3 gridsvgjs()

One of the goals of this package is to provide users and future contributors with simple, modular functions that can be inserted into more complex methods or serve as the foundation or inspiration for future components. This motivation was behind the decision to export the helper function `gridsvgjs()`. This function takes any grid based plot, converts it to SVG format (see section on `gridSVG`), inserts JavaScript for the Pan/Zoom functionality (see JavaScript Libraries section) and initiates a local Shiny instance. The four `display()` methods make use of the majority of the code in `gridsvgjs()`. After considering the potential usefulness of doing this with any plot, I repackaged the code as a stand-alone function. The standard R graphics viewer can sometimes be restrictive, particularly for larger plots. Viewing a plot as a vector based rendering with pan and zoom capabilities seemed to be a desirable addition to the package. The inserted JavaScript functionality is relatively simple, but hopefully it will encourage more interactivity in the future.

```
data(mtcars)
qp <- qplot(mpg, data=mtcars, geom="density", fill=factor(cyl), alpha=I(.4))
plot(qp)
```

To view the plot in the browser with JavaScript Pan/Zoom capabilities:

```
gridsvgjs(qp)
```

7 Special Mention Components

7.1 Shiny

The Shiny web framework is the component that was the main inspiration behind the proposal for this package. The relative simplicity of prototyping applications and its use of existing universal web standards makes it an enticing piece of software to build an open source package around. It means, unlike some packages built on low level code, there is a possibility for other biologists to contribute to the open source development. Shiny provides the web service and predefined UI elements, but relies on existing R packages to provide the data analysis and plotting. The interactivity of Shiny apps depends on its reactive programming model.

<http://shiny.rstudio.com/>

7.2 Gviz/ggbio

Gviz and ggbio provide the biology specific plots in the *GRanges* and *GRangesList* methods in interactiveDisplay. Both offer track-based plotting methods for genomic data. Gviz was the initial choice for *GRanges/GRangesList* trackplots because it offered more generic, extensible plotting. Later in development, ggbio plotting was also added as it handles additional complex plotting methods.

7.3 gridSVG

Simon Potter's `gridSVG` [5] is an important asset in developing interactive R plots. His package converts a grid [7] based plot to SVG format directly. Two major plotting packages for R, `lattice` [9] and `ggplot2` are built around grid (and many other packages depend on `ggplot2`), which gives `gridSVG` a lot of potential interaction with many Bioconductor libraries.

Figure 34: gridSVG [5]

8 JavaScript Libraries

8.1 Data-Driven Documents

Michael Bostock's JavaScript library, D3.js (<http://d3js.org/>), allows for highly customizable data visualizations using universal web standards. It can work along with Shiny to bind data to the Document Object Model (DOM). Unlike Shiny which handles the interactive elements but leaves R to handle the visualization, D3.js can handle both. Currently only the *ExpressionSet* method's Network View makes use of this library.

8.2 Zoom/Pan JavaScript libraries

This Zoom/Pan library is used in all four main `display()` methods and in `gridsvgjs()`. While a relatively simple feature, hopefully it will lead to more complex JavaScript interactivity that directly manipulates plots produced by R plotting packages. The Andrea Leofreddi's original JavaScript code was expanded upon by John Krauss to produce the version of this library used in *interactiveDisplay*.

John Krauss

<https://github.com/talos/jquery-svgpan>

8.3 JavaScript Color Chooser

The colorpicker included in the *ExpressionSet* method should eventually be moved into the Shiny package itself. Many R users outside of the Bioconductor community use RColorBrewer and could make use of this UI element in their Shiny based applications.
