Depends R (>= 3.5.0), graph

Description Pigengene package provides an efficient way to infer biological signatures from gene expression profiles. The signatures are independent from the underlying platform, e.g., the input can be microarray or RNA Seq data. It can even infer the signatures using data from one platform, and evaluate them on the other. Pigengene identifies the modules (clusters) of highly coexpressed genes using coexpression network analysis, summarizes the biological information of each module in an eigengene, learns a Bayesian network that models the probabilistic dependencies between modules, and builds a decision tree based on the expression of eigengenes.

Pigengene-package

Infers robust biological signatures from gene expression data

Description

Pigengene identifies gene modules (clusters), computes an eigengene for each module, and uses these biological signatures as features for classification. The resulting biological signatures are very robust with respect to the profiling platform. For instance, if Pigenegene computes a biological signature using a microarray dataset, it can infer the same signature in an RNA Seq dataset such that it is directly comparable across the two datasets.

Pigengene-package 3

Details

4 aml

Package: Pigengene
Type: Package
Version: 0.99.0
Date: 2016-04-25
License: GPL (>= 2)

The main function is one.step.pigengene which requires a gene expression profile and the corresponding conditions (types). Individual functions are provided to facilitate running the pipeline in a customized way. Also, the inferred biological signatures (computed eigengenes) are useful for other supervised or unsupervised analyses.

In most functions of this package, eigenegenes are computed or used as robust biological signatures. Briefly, each eigengene is a weighted average of the expression of all genes in a module (cluster), where the weights are adjusted in a way that the explained variance is maximized.

Examples

aml

AML gene expression profile

Description

Gene expression profile of 202 acute myeloid leukemia (AML) cases from Mills et al. study. The profile was compared with the profile of 164 myelodysplastic syndromes (MDS) cases and only the 1000 most differentially expressed genes are included.

balance 5

Usage

```
data("aml")
```

Format

A numeric matrix

Details

The columns and rows are named according to the genes Entrez, and patient IDs, respectively. The original data was produced using Affymetrix Human Genome U133 Plus 2.0 Miccoaray. Mills et al. study is part of the MILE Study (Microarray Innovations In LEukemia) program, and aimed at prediction of AML transformation in MDS.

Value

It is a 202*1000 numeric matrix.

```

balance

Balances the number of samples

Description

Oversamples data by repeating rows such that each condition has roughly the same number of samples.

Usage

```
balance(Data, Labels, amplification = 5, verbose = 0, naTolerance=0.05)
```

6 balance

Arguments

Data A matrix or data frame containing the expression data, with genes corresponding

to columns and rows corresponding to samples. Rows and columns must be

named.

Labels A (preferably named) vector containing the Labels (condition types) for Data.

Names must agree with rows of Data.

amplification An integer that controls the number of repeats for each condition. The number

of all samples roughly will be multiplied by this factor after oversampling.

verbose The integer level of verbosity. 0 means silent and higher values produce more

details of computation.

naTolerance Upper threshold on the fraction of entries per gene that can be missing. Genes

with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression

in the other samples. See check.pigengene.input.

Value

A list of:

balanced The matrix of oversampled data

Reptimes A vector of integers named by conditions reporting the number of repeats for

each condition.

origSampleInds The indices of rows in balanced that correspond to the original samples before

oversampling

```

calculate.beta 7

calculate.beta	Estimates an appropriate power value	
----------------	--------------------------------------	--

Description

The WGCNA package assumes that in the coexpression network the genes are connected with a power-law distribution. Therefore, it need a soft-thresholding power for network construction, which is estimated by this auxiliary function.

Usage

```
calculate.beta(saveFile = NULL, RsquaredCut = 0.8, Data, doThreads=FALSE,
  verbose = 0)
```

Arguments

saveFile The file to save the results in. Set to NULL to disable.

RsquaredCut A threshold in the range [0,1] used to estimate the power. A higher value can

increase power. For technical use only. See pickSoftThreshold for more de-

tails.

Data A matrix or data frame containing the expression data, with genes corresponding

to columns and rows corresponding to samples. Rows and columns must be

named.

doThreads Boolean. Allows WGCNA to run a little faster using multi-threading but might

not work on all systems.

verbose The integer level of verbosity. 0 means silent and higher values produce more

details of computation.

Value

A list of:

sft The full output of pickSoftThreshold function

power The estimated power (beta) value

powers The numeric vector of all tried powers

RsquaredCut The value of input argument RsquaredCut

8 check.nas

check.nas	Removes NAs from a data matrix	

Description

Checks Data for NA values.

Usage

```
check.nas(Data, naTolerance=0.05, na.rm=TRUE)
```

Arguments

Data A matrix or data frame containing the expression data, with genes corresponding

to columns and rows corresponding to samples. Rows and columns must be

named.

naTolerance A number in the 0-1 range. If the frequency of NAs in a column of Data is more

than this threshold, then that column will be removed.

na.rm If TRUE, NAs in the Data will be replaces with the average of the column, how-

ever, if the frequency of NAs in the column is too high (i.e., more than naTolerance),

the whole column will be removed.

Value

A list of:

cleaned The cleaned data with no NA value. Rows are the same as Data, but some

columns may be deleted.

tooNaGenes A character vector of those genes (i.e., column names of Data) that had too

many NAs, and therefore were removed.

replacedNaNum The number of NA entries in the matrix that were replaced with the average of

the corresponding column (gene).

```

check.pigengene.input 9

check.pigengene.input Quality check on the imput

Description

Checks Data and Labels for NA values, row and column names, etc.

Usage

```
check.pigengene.input(Data, Labels, na.rm = FALSE, naTolerance=0.05)
```

Arguments

Data A matrix or data frame containing the expression data, with genes corresponding

to columns and rows corresponding to samples. Rows and columns must be

named

Labels A (preferably named) vector containing the Labels (condition types) for Data.

Names must agree with rows of Data.

na.rm If TRUE, NAs in the Data will be replaces with the average of the column, how-

ever, if the frequency of NAs in the column is too high, the whole column will be

removed.

naTolerance Upper threshold on the fraction of entries per gene that can be missing. Genes

with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression

in the other samples. See check.pigengene.input.

Value

A list of:

Data The checked Data matrix, NA possibly removed and rows are ordered as names

of Labels.

Labels The checked vector of Labels

```

10 combine.networks

|--|--|--|--|--|

Description

Takes as input two or more adjacency matrices, and the corresponding contributions. Computes a combined network (weighted graph) in which the weight on an edge between two nodes is an average of the weights on the same edge in the input networks.

Usage

```
combine.networks(nets, contributions, outPath, midfix="",
    powerVector=1:20, verbose=1, RsquaredCut=0.75, minModuleSize=5,
   doRemoveTOM=TRUE, datExpr, doReturNetworks=FALSE)
```

Arguments

nets A list of adjacency matrices (networks), which can be generated using e.g., the

WGCNA::adjacency function. Rows and columns must be named.

A numeric vector with the same length as nets. In computing the average weight contributions

> on each edge in the combined network, first the edge weights from individual networks are multiplied by their corresponding contributions, then the result will

be divided by the sum of weights of all networks containing this edge.

outPath A string to the path where plots and results will be saved.

midfix An optional string used in the output file names.

powerVector A numeric vector of power values that are tried to find the best one. See WGCNA::pickSoftThreshold documentation.

verbose The integer level of verbosity. 0 means silent and higher values produce more

details of computation.

A threshold in the range [0,1] used to estimate the power. A higher value can RsquaredCut

increase power. For technical use only. See pickSoftThreshold for more de-

minModuleSize The value that controls the minimum number of genes per module.

doRemoveTOM A boolean determining the big TOM file must remove or not.

datExpr The expression matrix that WGCNA::blockwiseModules uses for fine-tuning and

removing genes from modules. This is not an ideal behavior by WGCNA.

doReturNetworks

A boolean value to determine whether to return Network, which is relatively a

big matrix (typically Gbs). Set to FALSE not to waste memory.

Value

A list with following components

call The command that created the results

midfix The input argument

The adjacency matrix of the combined network Network

compact.tree 11

denominators A matrix, each cell of which is the sum of weights of all networks contributing

to the edge corresponding to that cell

power The power (beta) value used for the combined network

fits The fit indices calculated for the combined network

net The output of WGCNA::blockwiseModules containing the module information

in its colors field

modules The output of WGCNA::blockwiseModules

combinedNetworkFile

The path to the saved file containing combinedNetwork

Note

If the networks have different node sets, the combined network will be computed on the union of nodes.

See Also

```
WGCNA::blockwiseModules, WGCNA::TOMsimilarity, and WGCNA::pickSoftThreshold.fromSimilarity
```

Examples

```
##--- Should be DIRECTLY executable !! ----
##-- ==> Define data, use random,
##--or do help(data=index) for the standard data sets.
## TODO, can be similar to the wgcna.one.step() example.
```

compact.tree

Reduces the number of genes in a decision tree

Description

In a greedy way, this function removes the genes with smaller weight one-by-one, while assessing the accuracy of the predictions of the resulting trees.

Usage

```
compact.tree(c5Tree, pigengene, Data=pigengene$Data, Labels=pigengene$Labels,
  testD=NULL, testL=NULL, saveDir=".", verbose=0)
```

Arguments

oFTmoo	A designan tree	s of along CEA that was	aa madula akaanaanaa	om NIIII I	TE VIIII TE
c5Tree	A decision free	t OF CIASS COW THAT HS	es module eigengenes	. OF NULL.	. II NULL. II

NULL, expression plots for all modules are created.

pigengene A object of pigengene-class, output of compute.pigengene

Data A matrix or data frame containing the expression data, with genes corresponding

to columns and rows corresponding to samples. Rows and columns must be

named.

Labels (condition types) for the (training) expression data. It is a named vector

of characters. Data will be subset according to these names.

12 compact.tree

testD The test expression data, for example, from an independent dataset. Optional.

testL Labels (condition types) for the (test) expression data. Optional.

saveDir Where to save the plots of the tree(s)

verbose Integer level of verbosity. 0 means silent and higher values produce more details

of computation.

Value

A list with following elements is invisibly returned:

call The call that created the results

predTrain Prediction using projected data without compacting

predTrainCompact

Prediction after compacting

genes A character vector of all genes in the full tree before compacting

genesCompacted A character vector of all genes in the compacted tree

trainErrors A matrix reporting errors on the train data. The rows are named according to

the number of removed genes. Each column reports the number of misclassified samples in one condition (type) except the last column that reports the total.

testErrors A matrix reporting errors on the test data similar to trainErrors

queue A numeric vector named by all genes contributing to the full tree before com-

pacting. The numeric values are weights increasingly ordered by absolute value.

pos The number of removed genes

txtFile Confusion matrices and other details on compacting are reported in this text file

Pigengene-package, compute.pigengene, make.decision.tree, C5.0, Pigengene-package

compute.pigengene 13

compute.pigengene (Computes the eigengenes	es

Description

This function takes as input the expression data and module assignments, and computes an eigengene for each module using PCA.

Usage

```
compute.pigengene(Data, Labels, modules, saveFile = "pigengene.RData",
    selectedModules = "All", amplification = 5, doPlot = TRUE,
    verbose = 0, dOrderByW = TRUE, naTolerance=0.05)
```

Arguments

Data	A matrix or data frame containing the training expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named.
Labels	A (preferably named) vector containing the Labels (condition types) for the training Data. Names must agree with rows of Data.
modules	A numeric vector, named by genes, that reports the module (clustering) assignments.
saveFile	The file to save the results. NULL will disable saving, and thus requires doPlot to be FALSE.
selectedModule	S
	A numeric vector determining which modules to use, or set to "All" (default) to include every module.
amplification	An integer that controls the number of repeats for each condition. The number of all samples roughly will be multiplied by this factor after oversampling. See balance.
doPlot	Boolean determining whether heatmaps of expression of eigengenes should be ploted and saved.
verbose	The integer level of verbosity. 0 means silent and higher values produce more details of computation.
dOrderByW	If TRUE, the genes will be ordered in the csv file based on their absolute weight in the corresponding module.
naTolerance	Upper threshold on the fraction of entries per gene that can be missing. Genes with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression in the other samples. See check.pigengene.input.

Details

Rows of Data are oversampled using balance so that each condition has roughly the same number of samples. moduleEigengenes computes an eigengene for each module using PCA.

Value

An object of pigengene-class.

14 dcor.matrix

Author(s)

Habil Zare and Amir Foroushani

References

Examples

dcor.matrix

Computes distance correlation for give matrix

Description

This function computes the distance correlation between every pair of columns of the input data matrix.

Usage

```
dcor.matrix(Data)
```

Arguments

Data

A matrix containing the data

Details

Using for loops, all pairs of columns are passed to link[energy]{dcor} function from link[energy]{energy-package

Value

A numeric square matrix. The number of rows and columns is equal to the number of columns of Data and they are named accordingly.

draw.bn 15

Note

This function uses for loops, which are not efficient for an input matrix with too many columns.

dcor1 <- dcor.matrix(Data=aml[,1:5])
dcor1

## Comparison with Pearson:
cor1 <- abs(cor(aml[,1:5]))
## With 202 samples, distance and Pearson correlations do not differ much:
dcor1-cor1
dcor2 <- dcor.matrix(Data=aml[1:20,1:5])
cor2 <- abs(cor(aml[1:20,1:5]))
## Distance correlation is more robust if fewer samples are available:
dcor2-cor2
plot(dcor2-cor1,cor1-cor2,xlim=c(-0.5,0.5),ylim=c(-0.5,0.5))</pre>
```

draw.bn

Draws a Bayesian network

Description

Draws the BN using appropriate colors and font size.

Usage

```
draw.bn(BN, plotFile = NULL, inputType = "ENTREZIDat", edgeColor = "blue",
  DiseaseCol = "darkgreen", DiseaseFill = "red", DiseaseChildFill = "pink",
  nodeCol = "darkgreen", nodeFill = "yellow", moduleNamesFile = NULL,
  mainText = NULL, nodeFontSize = 14 * 1.1, verbose = 0)
```

16 draw.bn

Arguments

BN An object of bn-class

plotFile If not NULL, the plot will be saved here.

inputType The type of gene IDs in BN

edgeColor The color of edges

DiseaseCol The color of the border of the Disease node

DiseaseFill The color of the area inside the Disease node

DiseaseChildFill

The color of the area inside the children of the Disease node

nodeCol The color of the border of the usual nodes excluding Disease and its children

nodeFill The color of the area inside the usual nodes

moduleNamesFile

An optional csv file including the information to rename the nodes name. See

coderename.node.

mainText The main text shown at the top of the plot

nodeFontSize Adjusts the size of nodes

verbose The integer level of verbosity. 0 means silent and higher values produce more

details of computation.

Value

A list with following components:

call The call that created the results

BN An echo of input BN argument

renamedBN An object of bn-class when moduleNamesFile is provided

gr The full output of graphviz.plot function

eigengenes33

eigengenes33

Eigengenes of 33 modules

Description

This list contains partial eigengenes computed from AML and MDS gene expression profiles provided by Mills et al. These data are included to illustrate how to use Pigengene-package and also to facilitate reproducing the results presented in the corresponding paper.

Usage

```
data(eigengenes33)
```

Format

A list

Details

The top 9166 differentially expressed genes were identified and their expressions in AML were used for identifying 33 modules. The first column, ME0, corresponds to module 0 (outliers) and is usually ignored. The eigengene for each module was obtained using compute.pigengene function. Oversampling was performed with amplification=5 to adjust for unbalanced sample-size.

Value

It is a list of 3 objects:

aml A 202 by 34 matrix. Each column reports the values of a module eigengene for AML cases.

mds A 164 by 34 matrix for MDS cases with columns similar to aml.

modules A numeric vector of length 9166 labeling members of each module. Named by Entrez ID.

Source

```

18 gene.mapping

gene.mapping	Maps gene IDs

Description

Takse as input gene IDs in a convention, say REFSEQ, and converts them to another convention.

Usage

```
gene.mapping(ids, inputType = "REFSEQ", outputType = "SYMBOL",
  leaveNA = TRUE, inputDb = "Human", outputDb = inputDb,
  verbose = 0)
```

Arguments

A character vector of input gene IDs
The type of input IDs.
The type of output IDs. If it is a character vector, mapping will be done for each element.
If TRUE, the IDs that were not matched are left with NAs in the second column of the output, otherwise the input IDs are returned.
The input data base. Use org.Hs.eg.db for human and org.Mm.eg.db for mouse. The default "Human" character uses the former.
The output data base. If it is a list, mapping will be done for each element.
The integer level of verbosity. 0 means silent and higher values produce more details of computation.

Details

It can map homologous genes between species e.g. from mouse to human. If more than 1 ID found for an input gene, only one of them is returned.

Value

A matrix of characters with 3 columns: input, output1, and output2. The last one is guaranteed not to be NA.

print(g1)

## Mapping to multiple convention
library(org.Mm.eg.db)
g2 <- gene.mapping(ids=c("NM_170730", "NM_001013580"),
    inputType="REFSEQ", inputDb=org.Mm.eg.db,
    outputType=c("SYMBOL","ENTREZID"),
    outputDb=list(org.Hs.eg.db,org.Mm.eg.db), verbose=1)
print(g2)</pre>
```

get.fitted.leaf

Returs the leaf for each sample

Description

Taking as input a tree and data, this function determines the leaf each sample will fall in.

Usage

```
get.fitted.leaf(c5Tree, inpDTemp, epsi = 10^(-7))
```

Arguments

c5Tree A decision tree of class C50 that uses module eigengenes, or NULL. If NULL,

expression plots for all modules are created.

inpDTemp The possibly new data matrix with samples on rows epsi A small perturbation to resolve the boundary issue

Value

A numeric vector of node indices named by samples (rows of inpDTemp)

Note

This function is tricky because C50 uses a global variable.

Author(s)

Amir Foroushani

20 get.genes

Examples

get.genes

List the (most relevant) genes for a decision tree.

Description

This function returns all genes that are left after shrinking (compacting) a given tree. If enhance is set to TRUE, it makes sure that the output contains at least two genes from each used module.

Usage

```
get.genes(c5Tree = NULL, pigengene = NULL, queue = NULL, modules = NULL, pos=0,
  enhance = TRUE)
```

Arguments

queue A character vector. The membership queue for a decsision tree.

pos Number of genes that are considered from removal. Same interpretation as in

preds.at

enhance If enhance is set to TRUE, the function makes sure that the output contains at least

two genes from each used module. Otherwise, exactly the pos first elements of

the queue are removed from consideration.

modules Named character vector listing the module assignments.

c5Tree A decision tree of class C50.

pigengene An object in pigengene-class, usually created by compute.pigengene.

Details

This function needs modules and queue, or alternatively, c5Tree and pigengene.

Value

A character vector containing the names of the genes involved in the modules whose eigengenes are used in the tree. If pos > 0, the first pos such genes with lowest absolute membership in their respective modules are filtered.

get.used.features 21

See Also

Pigengene-package, compact.tree,preds.at, get.used.features, make.decision.tree

Examples

```
## Data:
data(aml)
data(mds)
data(pigengene)
d1 <- rbind(aml,mds)

## Fiting the trees:
trees <- make.decision.tree(pigengene=pigengene, Data=d1,
saveDir="trees", minPerLeaf=15, doHeat=FALSE,verbose=3,
    toCompact=FALSE)
g1 <- get.genes(c5Tree=trees$c5Trees[["15"]],pigengene=pigengene)</pre>
```

get.used.features

Return the features used in a tree

Description

Only some of the features will be automatically selected and used in a decision tree. However, an object of class C5.0 does not have the selected feature names explicitly. This function parses the tree component and extracts the names of features contributing to the tree.

Usage

```
get.used.features(c5Tree)
```

Arguments

c5Tree

A decision tree of class 50

Value

A character vector of the names of features (module eigengenes) contributing to the input decision tree.

    saveDir="trees", minPerLeaf=15, doHeat=FALSE,verbose=3,
    toCompact=FALSE)
get.used.features(c5Tree=trees$c5Trees[["15"]])</pre>
```

learn.bn

Learns a Bayesian network

Description

This function takes as input the eigengenes of all modules and learns a Bayesian network using bnlearn package. It builds several individual networks from random staring networks by optimizing their score. Then, it infers a consensus network from the ones with relatively "higher" scores. The default hyper-parameters and arguments should be fine for most applications.

Usage

```
learn.bn(pigengene=NULL, Data=NULL, Labels=NULL, bnPath = "bn", bnNum = 100,
   consensusRatio = 1/3, consensusThresh = "Auto", doME0 = FALSE,
   selectedFeatures = NULL, trainingCases = "All", algo = "hc", scoring = "bde",
   restart = 0, pertFrac = 0.1, doShuffle = TRUE, use.Hartemink = TRUE,
   bnStartFile = "None", use.Disease = TRUE, use.Effect = FALSE, dummies = NULL,
   tasks = "All", onCluster = !(which.cluster()$cluster == "local"),
   inds = 1:ceiling(bnNum/perJob), perJob = 2, maxSeconds = 5 * 60,
   timeJob = "00:10:00", bnCalculationJob = NULL, seed = NULL, verbose = 0,
   naTolerance=0.05)
```

Arguments

pigengene	An object from pigengene-class. The output of compute.pigengene function.
Data	A matrix or data frame containing the training data with eigengenes corresponding to columns and rows corresponding to samples. Rows and columns must be named.
Labels	A (preferably named) vector containing the Labels (condition types) for the training data. Names must agree with rows of Data.
bnPath	The path to save the results
bnNum	The total number of individual networks. In practice, the number of learnt networks can be less than bnNum because some jobs may take too long and be terminated.

consensusRatio A numeric in the range 0-1 that determines what portion of highly scored networks should be used to build the consensus network

consensusThresh

A vector of thresholds in the range 0-1. For each threshold t, a consensus network will be build by considering the arcs that are present in at least a fraction of t of the individual networks. Alternatively, if it is "Auto" (the default), the threshold will be automatically set to the mean plus the standard deviation of the frequencies (strengths) of all arcs in the individual networks.

If TRUE, module 0 (the outliers) will be considered in learning the Bayesian network.

selectedFeatures

doME0

A character vector. If not NULL, only these features (eigengenes) will be used.

trainingCases A character vector that determines which cases (samples) should be considered

for learning the network.

algo The algorithm that bnlean uses for optimizing the score. The default is "hc" (hill

climbing). See arc. strength for other options and more details.

scoring A character determining the scoring criteria. Use 'bde' and 'bic' for the Bayesian

Dirichlet equivalent and Bayesian Information Criterion scores, respectively.

See score for technical details.

restart The number of random restarts. For technical use only. See hc.

pertFrac A numeric in the range 0-1 that determines the number of attempts to randomly

insert/remove/reverse an arc on every random restart. For technical use only.

doShuffle The ordering of the features (eigengenes) is important in making the initial net-

work. If doShuffle=TRUE, they will be shuffled before making every initial

network.

 ${\tt use.Hartemink} \quad \text{If TRUE, Hartemink algorithm will be used to discretize data. Otherwise, interval} \\$

discretization will be applied. See bnlearn: discretize.

bnStartFile Optionally, learning can start from a Bayesian network instead of a random net-

work. bnStartFile should contain a list called selected and selected\$BN should be an object of bn-class. Non-technical users can set to "None" to

disable.

use.Disease If TRUE, the condition variable Disease will be included in the network, which

cannot be the child of any other variable.

use.Effect If TRUE, the condition variable beAML will be included in the network, which

cannot be the parent of any other variable.

dummies A vector of numeric values in the range 0-1. Dummy random variables will be

added to the Bayesian network to check whether the learning process is effective.

For development purposes only.

tasks A character vector and a subset of c("learn", "harvest", "consensus", "graph")

that identifies the tasks to be done. Useful if part of the analysis was done pre-

viously, otherwise set to "All".

onCluster A Boolean variable that is FALSE if the learning is not done on a computer clus-

ter.

inds The indices of the jobs that are included in the analysis.

perJob The number of individual networks that are learnt by 1 job.

maxSeconds An integer limiting computation time for each training job that runs locally, i.e.,

when oncluster=FALSE.

timeJob The time in "hh: mm: ss" format requested for each job if they are running on a

computer cluster.

bnCalculationJob

A script used to submit jobs to the cluster. Set to NULL if not using a cluster.

seed The random seed that can be set to an integer to reproduce the same results.

verbose Integer level of verbosity. 0 means silent and higher values produce more details

of computation.

naTolerance Upper threshold on the fraction of entries per gene that can be missing. Genes

with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression

in the other samples. See check.pigengene.input.

Details

For learning a Bayesian network with tens of nodes (eigengenes), bnNum=1000 or higher is recommended. Increasing consensusThresh generally results in a network with fewer arcs. Nagarajan et al. proposed a fundamental approach that determines this hyper-parameter based on the background noise. They use non-parametric bootstrapping, which is not implemented in the current package yet.

The default values for the rest of the hyper-parameters should be fine for most applications.

Value

A list of:

consensusThresh

The vector of thresholds as described in the arguments.

indvPath The path where the individual networks were saved.

moduleFile The file containing data in appropriate format for bnlearn package and the black-

list arcs.

scoreFile The file containing the record of the successively jobs and the scores of the

corresponding individual networks.

consensusFile The file containing the consensus network and its BDe and BIC scores.

bnModuleRes The result of bn.module function. Useful mostly for development.

runs A list containing the record of successful jobs.

scores The list saved in scoreFile.

consensusThreshRes

The full output of consensus.thresh() function.

consensus 1 The consensus Bayesian network corresponding to the first threshold. It is the

output of consensus function and consensus1\$BN is an object of bn-class.

scorePlot The output of plot. scores functions, containing the scores of individual net-

works.

graphs The output of plot. graphS function, containing the BDe score of the consensus

network.

timeTaken An object of difftime-class recording the learning wall-time.

use.Disease, use.Effect, use.Hartemink

Some of the input arguments.

Note

Running the jobs on a cluster needs bnCalculationJob script, which is NOT included in the package yet.

26 make.decision.tree

make.decision.tree

Creates a decision tree to classify samples using the eigengenes values

Description

A decision tree in Pigengene-package uses module eigengenes to build a classifier that distinguishes the different classes. Briefly, each eigengene is a weighted average of the expression of all genes in the module, where the weight of each gene corresponds to its membership in the module.

Usage

Arguments

pigengene	The pigengene object that is used to build the decision tree. See pigengene-class.
-----------	--

Data The training expression data

Labels (condition types) for the (training) expression data. It is a named vector

of characters. Data and pigengene will be subset according to these names.

testD The test expression data, for example, from an independent dataset. Optional.

testL Labels (condition types) for the (test) expression data. Optional.

selectedFeatures

A numeric vector determining the subset of eigengenes that should be used as potential predictors. By default ("All"), eigengenes for all modules are consid-

ered. See also useMod0.

saveDir Where to save the plots of the tree(s).

minPerLeaf Vector of integers. For each value, a tree will be built requiring at least that

many nodes on each leaf. By default (NULL), several trees are built, one for each

possible value between 2 and 10 percent of the number of samples.

useMod0 Boolean. Wether to allow the tree(s) to use the eigengene of module 0, which

corresponds to the set of outlier, as a proper predictor.

costRatio A numeric value effective only for 2 groups classification. The default value

(1) considers the misclassification of both conditions as equally disadvatageous. Change this value to a larger or smaller value if you are more interested in the

specificity of predictions for condition 1 or condition 2, respectively.

toCompact An integer. The tree with this minPerLeaf value will be compacted (shrunk).

Compacting in this context means reducing the number of required genes for the calculation of the relevant eigengenes and making the predictions using the tree. If NULL (default), the (persumably) most general proper tree (corresponding to the largest value in the minPerLeaf vector for which a tree could be constructed)

is compacted. Set to FALSE to turn off compacting.

make.decision.tree 27

noise, noiseRepNum

For development purposes only. These parameters allow investigating the effect of gaussian noise in the expression data on the accurracy of the tree for test data.

doHeat Boolean. Set to FALSE not to plot the heatmaps for faster comoutation.

verbose The integer level of verbosity. 0 means silent and higher values produce more

details of computation.

naTolerance Upper threshold on the fraction of entries per gene that can be missing. Genes

with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression

in the other samples. See check.pigengene.input.

Details

This function passes the inut eigengenes and appropriate arguments C5.0 function from C50 package.

Value

A list with following elements:

call The call that created the results

c5Trees A list, with one element of class C5.0 for each attempted minNodesperleaf

value. The list is named with the corresponding values as characters.

minPerLeaf A numeric vector enumerating all of the attempted minPerLeaf values.

compacted The full output of compact.tree function if toCompact is not FALSE

heat The output of module. heatmap function for the full tree if doHeat is not FALSE

heatCompact The output of module.heatmap function for the compacted tree if toCompact is

not FALSE

noisy The full output of noise analysiy function if noise is not 0. For development

and evaluation purposes only.

leafLocs A matrix reporting the leaf for each sample on 1 row. The columns are named

according to the correspoding minNodesperleaf value.

toCompact Echos the toCompact input argument

costs The cost matrix

saveDir The directory where plots are saved in

Note

For faster computation in an initial, explanatory run, turn off compacting, which can take a few minutes, with toCompact=FALSE.

Examples

mds

MDS gene expression profile

Description

Gene expression profile of 164 myelodysplastic syndromes (MDS) cases from Mills et al. study. The profile was compared with the profile of 202 acute myeloid leukemia (AML) cases and only the 1000 most differentially expressed genes are included.

Usage

```
data("mds")
```

Format

A numeric matrix

Details

The columns and rows are named according to the genes Entrez, and patient IDs, respectively. The original data was produced using Affymetrix Human Genome U133 Plus 2.0 Miccoaray.Mills et al. study is part of the MILE Study (Microarray Innovations In LEukemia) program, and aimed at prediction of AML transformation in MDS.

Value

It is a 164*1000 numeric matrix.

Note

This profile includes data of the 25 chronic myelomonocytic leukemia (CMLL) cases that can have different expression signatures according to Mills et al.

Examples

```
library(pheatmap)
data(mds)
pheatmap(mds[,1:20],show_rownames=FALSE)
```

message.if

Conditional messaging.

Description

Messages only if verbose is more than 0

Usage

```
message.if(me = NULL, verbose = 0)
```

Arguments

me The Message.
verbose A integer.

Value

NULL

Author(s)

Amir Foroushani

Examples

```
message.if("Hello world!", verbose=1)
```

module.heatmap

Plots heatmaps for modules

Description

This function takes as input a tree and an object from pigengene-class and per any module used in the tree, it plots one gene expression heatmap.

Usage

```
module.heatmap(c5Tree, pigengene, saveDir, testD = NULL,
  testL = NULL, pos = 0, verbose=0, doAddEigengene=TRUE, scalePngs=1, ...)
```

30 module.heatmap

Arguments

c5Tree A decision tree of class C50 that uses module eigengenes, or NULL. If NULL,

expression plots for all modules are created.

pigengene A object of pigengene-class, output of compute.pigengene

saveDir Directory to save the plots

testD, testL Optional. The matrix of (independent) test expression data and the correspond-

ing vector of labels

pos Number of genes to discard. Interpreted the same way as in compact.tree ad

preds.at

verbose The integer level of verbosity. 0 means silent and higher values produce more

details of computation.

doAddEigengene If TRUE, the eigengene of each module will be added to the corresponding heatmap.

scalePngs If not 1, the size of pngs will be adjusted using this parameter. A typical value

would be 7.

... Additional arguments. Passed to pheatmap.type

Value

A list of:

call The call that created the results

saveDir An echo of the input argument determining where the plots are saved

See Also

Pigengene-package, make.decision.tree, compact.tree, compute.pigengene

one.step.pigengene 31

ne.step.pigengene Runs the entire Pigengene pipeline
--

Description

Runs the entire Pigengene pipeline, from gene expression to compact decision trees in a single function. It identifies the gene modules using coexpression network analysis, computes eigengenes, learns a Bayesian network, fits decision trees, and compact them.

Usage

```
one.step.pigengene(Data, saveDir = "Pigengene", Labels, testD = NULL,
testLabels = NULL, doBalance = TRUE, RsquaredCut=0.8, costRatio = 1, toCompact = FALSE, bnNum = 0,
bnArgs = NULL, useMod0 = FALSE, mit = "All", verbose = 0, doHeat = TRUE,
seed = NULL, dOrderByW = TRUE, naTolerance=0.05)
```

Arguments

Data	A matrix or data frame (or list of matrices or data frames) containing the training expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. For example, from RNA-Seq data, log(RPKM+1) can be used.
Labels	A (preferably named) vector containing the Labels (condition types) for the training Data. Or, if Data is a list, a list of label vectors corresponding to the data sets in Data. Names must agree with rows of Data.
saveDir	Directory to save the results.
testD	Test expression data with syntax similar to Data, possibly with different rows and columns.
testLabels	A (preferably named) vector containing the Labels (condition types) for the test Data.
doBalance	Boolean. Whether the data should be oversampled before identifying the modules so that each condition contribute roughly the same number of samples to clustering.
RsquaredCut	A threshold in the range [0,1] used to estimate the power. A higher value can increase power. For technical use only. See pickSoftThreshold for more details.
costRatio	A numeric value, the relative cost of misclassifying a sample from the first condition vs. misclassifying a sample from the second condition.
toCompact	An integer value determining which decision tree to shrink. It is the minimum number of genes per leaf imposed when fitting the tree. Set to FALSE to skip compacting, to NULL to automatically select the maximum value.
bnNum	Desired number of bootstraped Baysian networks. Set to 0 to skip BN learning.
bnArgs	A list of arguments passed to learn. bn function.
useMod0	Boolean, whether to allow module zero (the set of outliers) to be used as a predictor in the decision tree(s).
mit	The "module identification type", a character vector determining the reference conditions for clustering. If 'All' (default), clustering is performed using the entire data regardless of condition.

32 one.step.pigengene

verbose The integer level of verbosity. 0 means silent and higher values produce more

details of computation.

doHeat If TRUE the heatmap of expression of genes in the modules that contribute to the

the tree will be plotted.

seed Random seed to ensure reproducibility.

dOrderByW If TRUE, the genes will be ordered in the csv file based on their absolute weight

in the corresponding module.

naTolerance Upper threshold on the fraction of entries per gene that can be missing. Genes

with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression

in the other samples. See check.pigengene.input.

Details

This is the main function of the package Pigengene and performs several steps: First, modules are identified in the training expression data, according to mit argument i.e. based on coexpression behaviour in the corresponding conditions. Set it to "All" to use all training data for this step regardless of the condition. Then, if a list of data frames is provided in Data, similarity networks on the data sets are computed and combined into one similarity network for the union of nodes across data sets. Then, the eigengenes for each module and each sample are calculated, where the expression of an eigengene of a module in a sample is the weighted average of the expression of the genes in that module in the sample. Technically, an eigengene is the first principal component of the gene expression in a module. PCA ensures that the maximum variance accross all the training samples is explained by the eigengene. Next, (optionally -if bnNum is set to a value greater than 0), several bootstrapped Bayesian networks are learned and combined into a consensus network, in order to detect and illustrate the probabilistic dependencies between the eigengenes and the disease subtype. Next, decisision tree(s) are built that use the module eigengenes, or a subset of them, to distinguish the classes (Labels). The accurracy of trees is assessed on the train and (if provided) test data. Finally, the number of required genes for the calculation of the relevant eigengenes is reduced (the tree is 'compacted'). The accuracy of the tree is reassessed after removal of each gene. Along the way, several self explanatory directories, heatmaps and plots are created and stored under saveDir.

Value

A list with the following components:

call The call that created the results.

wgRes A list. The results of WGCNA clustering of the Data by wgcna.one.step.

betaRes A list. The automatically selected beta (power) parameter which was used for

the WGCNA clustering. It is the result of the call to ${\tt calculate.beta}$ using the

 $expression \ data \ of \ \mbox{mit} \ conditions (s).$

pigengene The pigengene object computed for the clusters, result of compute.pigengene.

learntBn A list. The results of learn.bn call for learning a Bayesian network using the

eigengenes.

selectedFeatures

A vector of the names of module eigengenes that were considered during the construction of decision trees. If bnNum >0, this corresponds to the immediate

neighbors of the Disease or Effect variable in the consensus network.

c5treeRes A list. The results of make.decision.tree call for learning decision trees that

use the eigengenes as features.

pheatmap.type 33

Note

The individual functions are exported to facilitated running the pipeline step-by-step in a customized way.

```

Examples

pheatmap.type

Plots heatmap with clustering only within types.

Description

This function first performs hierarchical clustering on samples (rows of data) within each condition. Then, plots a heatmap without further clustering of rows.

Usage

```
pheatmap.type(Data, annRow, type = colnames(annRow)[1],
doTranspose=FALSE, conditions="Auto",...)
```

Arguments

Data A matrix with samples on rows and features (genes) on columns.

annRow A data frame with 1 column or more. Row names must be the same as row

names of Data.

type The column of annRow used for determining the condition

doTranspose If TRUE, the matrix will be transposed for the final plot. E.g., if the genes are on

the columns of Data, they will be shown on rows of the heatmap.

34 pigengene

conditions A character vector that determines the conditions, and their order, to be included

in the heatmap. By default ("Auto"), an alphabetical order of all available con-

ditions in annRow will be used.

. . . Additional arguments passed to pheatmap function.

Value

A list of:

pheatmapS The results of pheatmap function for each condition
pheat The output of final pheatmap function applied on all data

ordering The ordering of the rows in the final heatmap annRowAll The row annotation used in the final heatmap

Note

If type is not determined, by default the first column of annRow is used.

pigengene

An object of class Pigengene

Description

This is a toy example object of class pigengene-class. It is used in examples of Pigengene-package. Gene expression profile of 202 acute myeloid leukemia (AML) cases from Mills et al. study. The profile was compared with the profile of 164 myelodysplastic syndromes (MDS) cases and only the 1000 most differentially expressed genes are included.

Usage

```
data("aml")
```

Format

An object of pigengene-class.

pigengene-class 35

Details

The object is made using compute.pigengene function from aml and mds data as shown in the examples. The R CMD build --resave-data trick was used to reduce the size of saved object from 3.1 MB to 1.4 MB.

Value

It is an object of pigengene-class.

```

pigengene-class

The pigengene class

Description

A pigengene object holds the eigengenes, weights (memberships) and other related information.

36 plot.pigengene

Details

A object of class pigengene is the output of compute.pigengene function. It is a list containing at least the following components:

- call The call that created the results.
- Reptimes A named vector reporting the number of repeats for each condition in the oversampling process, which is done by the balance function.
- eigenResults The full output of moduleEigengenes function.
- Data The data matrix of gene expression.
- Labels A character vector giving the condition (type) for each sample (row of Data).
- eigengenes The matrix of eigengenes ordered based on selectedModules if provided.
- membership The matrix of weights of genes (rows) in all modules (columns).
- orderedModules The module assignment numeric vector named with genes and ordered based on module number.
- annotation A data frame containing labeling information useful in plotting. It has one column named "Condition". Rows have sample names.
- saveFile The file where the pigengene object is saved.
- weightsCsvFile The file containing the weights in csv format. See dOrderByW=TRUE.
- weights The weight matrix, which is also saved in csv format. It has more columns than membership but rows may be in a different order if dOrderByW=TRUE.
- heavyToLow If dOrderByW=TRUE, this will be the ordering of genes according to the modules
 the belong to, where the genes in each module are ordered based on the absolute value of the
 weights in that module. Also, the genes in the csv file are in this order.

For 2 or more groups (conditions), additional (optional) components include:

- pvalues A numeric matrix with columns "pValue", "FDR", and "Bonferroni". Rows correspond to modules. The null hypothesis is that the eigengene is expressed with the same distribution in all groups (conditions).
- log.pvalues A data frame with 1 column containing the logarithm of Bonferroni-adjusted pvalues in base 10.

plot.pigengene

Plots and saves a pigengene object

Description

Plots a couple of heatmaps of expression of the eigengenes, weights (memberships), and so on. Saves the plots in png format.

plot.pigengene 37

Usage

```
## S3 method for class 'pigengene'
plot(x, saveDir = NULL,
   DiseaseColors = c("red", "cyan"),
   fontsize = 35, doShowColnames = TRUE, fontsizeCol = 25,
   doClusterCols = ncol(pigengene$eigengenes) > 1,
   verbose = 2, doShowRownames = "Auto",
   pngfactor = max(2, ncol(pigengene$eigengenes)/16), do0Mem = FALSE, ...)
```

Arguments

The object from pigengene-class computed by compute.pigengene.

saveDir The directory for saving the plots

DiseaseColors A vector of characters determining color for each disease

fontsize Passd to pheatmap.type

doShowColnames Boolean fontsizeCol Numeric doClusterCols Boolean

verbose The integer level of verbosity. 0 means silent and higher values produce more

details of computation.

doShowRownames Boolean

pngfactor A numeric adjusting the size of the png files

do@Mem If TRUE, module 0 genes are included in the membership heatmap.

... Passd to pheatmap.type function

Details

Many of the arguments are passed to pheatmap.

Value

A list of:

heat The full output of pheatmap functionion
heatNotRows The full output of pheatmap.type function

Author(s)

Habil Zare ad Amir Foroushani

Prediction using a possibly compacted tree

Description

A decision tree in Pigengene uses module eigengenes to build a classifier that distincuishes two or more classes. Each eigengene is a weighted average of the expression of all genes in the module, where the weight of each gene corresponds to its membership in the module. Each modules might contain dozens to hundreds of genes, and hence the final classifier might depend on the expression of a large number of genes. In practice, it can be desireable to reduce the number of necessary genes used by a decision tree. This function is helpful in observing changes to the classification output after removing genes with lower weights membership. It determines how a given decision tree would classify the expression data after removing a certain number of genes from consideration.

Usage

```
preds.at(c5Tree, pigengene, pos=0, Data)
```

Arguments

c5Tree A decision tree that uses eigengenes from the pigengene object to classify the

samples from the expression data.

pigengene A object of pigengene-class, output of compute.pigengene

pos Number of genes to be removed from the consideration. Genes are removed in

ascending order of their absolute weight in the relevant modules. If 0 (default),

the prediction will be done without compacting.

Data The expression possibly new data used for classification

Value

A list with following components:

predictions The vector of predictions after neglecting pos number of genes eigengenes The values for the eigenges after neglecting pos number of genes project.eigen 39

Examples

project.eigen

Infers eigengenes for given expression data

Description

This function projects (new) expression data onto the eigengenes of modules from another dataset. It is usfull for comparing the expression behaviour of modules across (biologically related yet independent) datasets, for evaluating the performance of a classifier on new datasets, and for examining the robustness of a pattern with regards to missing genes.

Usage

```
project.eigen(Data, saveFile = NULL, pigengene, naTolerance = 0.05,
  verbose = 0, ignoreModules = c())
```

Arguments

Data A matrix or data frame of expression data to be projected. Genes correspond to

columns, and rows correspond to samples. Rows and columns must be named. It is OK to miss a few genes originally used to compute the eigengenes, thereby,

projection is robust to choose of platform.

saveFile If not NULL, where to save the results in .RData format.

pigengene An object of pigengene-class, usually created by compute.pigengene

naTolerance Upper threshold on the fraction of entries per gene that can be missing. Genes

with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression

in the other samples. See check.pigengene.input.

verbose The integer level of verbosity. 0 means silent and higher values produce more

details of computation.

ignoreModules A vector of integers. In order to speed up the projection, it may be desirable

to focus only on the eigengenes of a few interesting modules. In that case, the remaining modules can be listed here and will be ignored during projection

(Optional).

40 project.eigen

Details

For each module, from the pigengene object, the weight (membership) of each gene is retrieved. The eigengene is computed (inferred) on the new data as alinear combination using the corresponding weights. The inferred eigengene vector will be normalized so that it has the same Euclidean norm as the original eigengene vector.

Value

A list of:

projected The matrix of inferred (projected) eigengenes

replacedNaNum The number of NA entries in the input Data that were replaced with the the

average expression of the corresponding gene

tooNaGenes A character vector of genes that were ignored because they had too many NAs

notMatched A character vector of genes in the original eigengene that could not be matched

in the given input Data

Note

The new data should use the same type of biolocal identifiers (e.g. Gene Symbols or ENTREZIDs) as the original data for which the pigengene was constructed. It is, however, not required that the new data originate from the same type of technology, e.g. the eigengenes can be based on microarray experiments, whereas the new data comes from an RNA-Seq experiment. Nor is it necessary that the new datset contains measurements for all of the genes from the original modules.

## Data:
data(aml)
data(mds)
data(eigengenes33)
d1 <- rbind(aml,mds)
Labels <- c(rep("AML",nrow(aml)),rep("MDS",nrow(mds)))
names(Labels) <- rownames(d1)
toyModules <- eigengenes33$modules[colnames(d1)]
## Computing:
p1 <- compute.pigengene(Data=d1, Labels=Labels, modules=toyModules, saveFile="pigengene.RData", doPlot=TRUE, verbose=3)
## How robust projecting is?
p2 <- project.eigen(Data=d1, pigengene = p1, verbose = 1)
plot(p1$eigengenes[,"ME1"],p2$projected[,"ME1"])
cor(p1$eigengenes[,"ME1"],p2$projected[,"ME1"])</pre>
```

pvalues.manova 41

pvalues.manova	Computes pvalues for multi-class differential expression

Description

Passes the arguments to manova, which performs multi-class analysis of variance.

Usage

```
pvalues.manova(Data, Labels)
```

Arguments

Data A matrix or data frame containing the (expression) data, with genes correspond-

ing to columns and rows corresponding to samples. Rows and columns must be

named.

Labels A (preferably named) vector containing the Labels (condition types). Names

must agree with rows of Data

Value

A list with following elements:

call The call that created the results

pvals The matrix of pvalues with columns "pValue", "FDR", "Bonferroni". Rows are

named according to genes, the columns of Data.

manovaFit The full output of manova function.

Note

oneway. test function is a better generalizatoion to Welch's t-tst from 2-calsses to multi-class because it dose not assume that the variaces are necessarly equal. However, in practice, with "enough number of samples", the two approaches will lead to similar p-values.

Examples

```
data(eigengenes33)
d1 <- rbind(eigengenes33$aml,eigengenes33$mds)
Labels <- c(rep("AML",nrow(eigengenes33$aml)),rep("MDS",nrow(eigengenes33$mds)))
names(Labels) <- rownames(d1)
ps <- pvalues.manova(Data=d1, Labels=Labels)
plot(log10(ps$pvals[,"Bonferroni"]))</pre>
```

save.if

Saves an object verbosely.

Description

Saves an R object, and reports the size of the saved object in memory and on file.

Usage

```
save.if(x1, file, verbose = 1)
```

Arguments

x1 The object to be saved.

file Where to save. If NULL, nothing will be saved.

verbose A numeric determining how much detail will be printed.

Value

A list including file, and a vector of sizes of the object in memory and on file.

wgcna.one.step 43

Module identification

Description

This function is a wrapper function for blockwiseModules and passes its arguments to it. Some other arguments are fixed.

Usage

```
wgcna.one.step(Data, power, saveDir=".", blockSize = "All", saveTOMs = FALSE,
doThreads=FALSE, verbose = 0, seed = NULL)
```

Arguments

Data	A matrix or data frame containing the expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named.
power	Soft-thresholding power for network construction
saveDir	The directory to save the results and plots. NULL will disable saving.
blockSize	The size of block when the data is too big. If not "All" (default) may introduce artifacts.
saveTOMs	Boolean determining if the TOM data should be saved, which can be hundreds of MBs and useful for identifying hubs.
doThreads	Boolean. Allows WGCNA to run a little faster using multi-threading but might not work on all systems.
verbose	The integer level of verbosity. 0 means silent and higher values produce more details of computation.
seed	Random seed to ensure reproducibility.

Details

Data, power, blockSize, saveTOMs, verbose, and seed are passd to blockwiseModules.

Value

A list with following components

call	The command that created the results
genes	The names of Data columns
modules	A numeric vector, named by genes, that reports the module (clustering) assignments.
moduleColors	A character vector, named by genes, that reports the color of each gene according to its module assignment
net	The full output of blockwiseModules function
netFile	The file in which the net object is saved
power	An echo of the power argument.
