# Package 'strandCheckR' 

October 17, 2020
Type PackageTitle Calculate strandness information of a bam fileVersion 1.6.0
Maintainer Thu-Hien To [tothuhien@gmail.com](mailto:tothuhien@gmail.com)
Description This package aims to quantify and remove putative double strand DNA from a strand-specific RNA sample. There are also options and methods to plot the positive/negative propor-tions of all sliding windows, which allow users to have an idea of how much the sample was con-taminated and the appropriate threshold to be used for filtering.

strandCheckR-package Quantify and Filter putative double strand DNA from strand-specific RNA bam file

## Description

This package aims to quantify and remove putative double strand DNA from a strand-specific RNA sample. There are also options and methods to plot the positive/negative proportions of all sliding windows, which allow users to have an idea of how much the sample was contaminated and the appropriate threshold to be used for filtering.

## Details

The package has some following main functions:

- getWinFromBamFile: calculate positive/negative proprortion and sum of reads over all sliding windows from a bam file
- plotHist: plot histogram of positive proportion of windows calculated from getWinFromBamFile method
- plotWin: plot positive proportion vs number of reads of windows calculated from getWinFromBamFile method
- filterDNA: filter a bam file

## Author(s)

Thu-Hien To \& Steve Pederson
Maintainer: Hien To <hien.to@ adelaide.edu.au>

## Examples

```
bamfilein <- system.file("extdata","s1.sorted.bam",package = "strandCheckR")
windows <- getWinFromBamFile(bamfilein)
plotWin(windows)
plotHist(windows)
filterDNA(file = bamfilein,destination = "filter.bam")
```

```
calculateStrandCoverage
```

    Calculate the strand information based on coverage
    
## Description

Calculate the coverage coming from ' $+\prime /$ ' - ' reads in all sliding wndows

## Usage

calculateStrandCoverage(winPosAlignments, winNegAlignments, winWidth = 1000, winStep = 100)

## Arguments

winPosAlignments
a list that has a "Coverage' field containing coverage coming from positive reads
winNegAlignments
a list that has a 'Coverage' field containing coverage coming from negative reads
winWidth the length of the sliding window, 1000 by default.
winStep the step length to sliding the window, 100 by default.

## Value

a list of two vectors, containing a positive/negative coverage of the input positive/negative windows

```
calculateStrandNbReads
```

Calculate the strand information based the number of reads

## Description

Calculate the number of reads coming from ' + ' $/$ '-' strands in all sliding wndows

## Usage

calculateStrandNbReads(winPosAlignments, winNegAlignments)

## Arguments

winPosAlignments
a list that has a 'Win' field that contains information of sliding windows overalapping positive reads
winNegAlignments
a a list that has a 'Win' field that contains information of sliding windows overalapping negative reads

## Value

a list of two vectors, containing a positive/negative number of reads of the input positive/negative windows
checkPairedEnd Test whether a bam file if single end or paired end

## Description

Check the first 100000 first reads of the bam file to see whether it is single end or paired end

## Usage

checkPairedEnd(file, yieldSize = 1e+05)

## Arguments

file the input bam file. Your bamfile should be sorted and have an index file located at the same path as well.
yieldSize the number of reads to be checked, 100000 by default.

## Value

return TRUE if the input file is paired end, and FALSE if it is single end

## Examples

```
file <- system.file('extdata','s1.sorted.bam',package = 'strandCheckR')
checkPairedEnd(file)
```

concatenateAlignments Concatenate a list of Alignments into One

## Description

Concatenate a list of Alignments from multiple sequences into a single object

## Usage

concatenateAlignments(readInfo, seqInfo)

## Arguments

readInfo a list returned by scanBam function, each element correspond to a sequence, containing the information of strand, starting position, cigar string, and eventually flag, qname
seqInfo a data frame that contains some key information of the alignments

## Details

This method take a list of alignments across one or more sequences as output by scanBam and concatenates them into a single set of alignments which may include multiple sequences

## Value

the concatenated alignments of the input list

## Description

Filter putative double strand DNA from a strand specific RNA-seq using a window sliding across the genome.

## Usage

```
filterDNA(file, destination, statfile, sequences, mapqFilter = 0, paired,
yieldSize = 1e+06, winWidth = 1000, winStep = 100, readProp = 0.5,
threshold = 0.7, pvalueThreshold = 0.05, useCoverage = FALSE,
mustKeepRanges, getWin = FALSE, minCov = 0, maxCov = 0,
errorRate = 0.01)
```

## Arguments

| file | the input bam file to be filterd. Your bamfile should be sorted and have an index <br> file located at the same path. |
| :--- | :--- |
| destination | The file path where the filtered output will be written <br> the file to write the summary of the results |
| statfile | the list of sequences to be filtered. |
| sequences |  |
| every read that has mapping quality below mapqFilter will be removed before |  |
| any analysis If missing, the entire bam file will be read. |  |
| if TRUE then the input bamfile will be considered as paired end reads. If miss- |  |
| ing, 100 thousands first reads will be inspected to test if the input bam file in |  |
| paired end or single end. |  |
| by default is 1e6, i.e. the bam file is read by block of records whose size is |  |
| defined by this paramter. It is used to pass to same paramter of the scanBam |  |
| function. |  |
| paired |  |

| minCov | if useCoverage=FALSE, every window that has less than minCov reads will be <br> rejected regardless the strand proportion. If useCoverage=TRUE, every window <br> has max coverage least than minCov will be rejected. 0 by default |
| :--- | :--- |
| maxCov | if useCoverage=FALSE, every window that has more than maxCov reads will <br> be kept regardless the strand proportion. If useCoverage=TRUE, every window <br> with max coverage more than maxCov will be kept. If 0 then it doesn't have <br> effect on selecting window. 0 by default. |
| errorRate | the probability that an RNA read takes the false strand. 0.01 by default. |

## Details

filterDNA reads a bam file containing strand specific RNA reads, and filter reads coming from putative double strand DNA. Using a window sliding across the genome, we calculate the positive/negative proportion of reads in each window. We then use logistic regression to estimate the strand proportion of reads in each window, and calculate the p-value when comparing that to a given threshold. Let $\pi$ be the strand proportion of reads in a window.
Null hypothesis for positive window: $\pi \leq$ threshold.
Null hypothesis for negative window: $\pi \geq 1$-threshold.
Only windows with p-value <= pvalueThreshold are kept. For a kept positive window, each positive read in this window is kept with the probability $(\mathrm{P}-\mathrm{M}) / \mathrm{P}$ where P be the number of positive reads, and $M$ be the number of negative reads. That is because those $M$ negative reads are supposed to come from double-strand DNA, then there should be also M postive reads among the P positive reads come from double-strand DNA. In other words, there are only ( $\mathrm{P}-\mathrm{M}$ ) positive reads come from RNA. Each negative read is kept with the probability equalling the rate that an RNA read of your sample has wrong strand, which is errorRate. Similar for kept negative windows.

Since each alignment can be belonged to several windows, then the probability of keeping an alignment is the maximum probability defined by all windows that contain it.

## Value

if getWin is TRUE: a DataFrame object which could also be obtained by the function getWinFromBamFile

## See Also

getWinFromBamFile, plotHist, plotWin

## Examples

```
file <- system.file('extdata','s2.sorted.bam',package = 'strandCheckR')
filterDNA(file,sequences='10',destination='out.bam')
```

getWinFromBamFile get the strand information of all windows from bam files

## Description

get the number of positive/negative reads of all windows from bam files

## Usage

getWinFromBamFile(files, sequences, mapqFilter $=0$, yieldSize $=1 \mathrm{e}+06$, winWidth $=1000$, winStep $=100$, readProp $=0.5$, paired)

## Arguments

files the input bam files. Your bamfiles should be sorted and have their index files located at the same path.
sequences the list of sequences to be read
mapqFilter every read that has mapping quality below mapqFilter will be removed before any analysis
yieldSize by default is 1e6, i.e. the bam file is read by block of records whose size is defined by this paramter. It is used to pass to same paramter of the scanBam function.
winWidth the width of the sliding window, 1000 by default.
winStep the step length to sliding the window, 100 by default.
readProp A read is considered to be included in a window if at least readProp of it is in the window. Specified as a proportion. 0.5 by default.
paired if TRUE then the input bamfile will be considered as paired end reads. If missing, 100 thousands first reads will be inspected to test if the input bam file in paired end or single end.

## Value

a DataFrame object containing the number of positive/negative reads and coverage of each window sliding across the bam file

## See Also

```
filterDNA, plotHist, plotWin
```

## Examples

```
file <- system.file('extdata','s1.sorted.bam',package = 'strandCheckR')
win <- getWinFromBamFile(file,sequences='10')
win
```

getWinFromGranges Get the Sliding Windows from a GRanges object

## Description

Get the positive/negative windows that overlap a GRanges object

## Usage

```
getWinFromGranges(x, seqInfo, winWidth = 1000, winStep = 100)
```

## Arguments

X
seqInfo a data frame that contains some key information of the alignments
winWidth The width of each window
winStep $\quad$ The step size for sliding the window

## Value

A list of two logical vectors (for positive and negative strand) defining which windows that overlap the given Granges objects

```
getWinFromIRanges Get the Ranges of Sliding Windows from an IRanges object
```

## Description

Get the Ranges of Sliding Windows from an IRanges object

## Usage

getWinFromIRanges(x, winWidth = 1000L, winStep = 100L, readProp = 0.5, maxWin = Inf)

## Arguments

X
winWidth
winStep
maxWin
readProp A read is considered to be included in a window if at least readProp of it is in the window. Specified as a proportion.
an IRanges object containing the start and end position of each read fragment The width of each window The step size for sliding the window

The maximum window ID

## Details

This finds the windows that overlap each fragment of a read and returns a range containing this list of windows for each read fragment. This allows the total number of read fragments within a window to be calculated simply using coverage.

## Value

An IRanges object containing the index of the windows containing each read fragment

```
getWinFromReadInfo get the strand information of all windows from read information
```

## Description

get the number of positive/negative reads of all windows from read information obtained from scanBam function

## Usage

getWinFromReadInfo(readInfo, winWidth = 1000, winStep = 100, readProp $=0.5$, subset $=$ NULL)

## Arguments

| readInfo | a list contains read information returned by scanBam function when read a bam <br> file |
| :--- | :--- |
| winWidth | the width of the sliding window, 1000 by default. |
| winStep | the step length to sliding the window, 100 by default. |
| readProp | A read is considered to be included in a window if at least readProp of it is in <br> the window. Specified as a proportion. 0.5 by default. |
| subset | an integer vector specifying the subset of reads to consider |

## Value

a DataFrame object containing the number of positive/negative reads and coverage of each window sliding

## See Also

filterDNA, getWinFromBamFile

```
getWinOfAlignments get the window ranges of alignments
```

## Description

calculate the windows that contain each read fragment

## Usage

getWinOfAlignments(readInfo, strand, winWidth, winStep, readProp, useCoverage $=$ FALSE, subset $=$ NULL)

## Arguments

| readInfo | a list contains the read information of one sequence |
| :--- | :--- |
| strand | the considering strand |
| winWidth | the window size |
| winStep | the window winStep |
| readProp | a read is considered to be included in a window if and only if at least readProp <br> percent of it is in the window. |
| useCoverage | either base on coverage or number of reads |
| subset | if we consider only a subset of the input reads |

## Value

If useCoverage=FALSE: an IRanges object which contains the range of sliding windows that overlap each read fragment. If useCoverage=TRUE: a list of two objects, the first one is the later IRanges object, the second one is an integer-Rle object which contains the coverage of the input readInfo
intersectWi thFeature Intersect the windows data frame with an annotation data frame

## Description

Intersect the windows with an annotation data frame to get features that overlap with each window

## Usage

intersectWithFeature(windows, annotation, getFeatureInfo = FALSE, overlapCol = "OverlapFeature", mcolsAnnot, collapse, ...)

## Arguments

windows data frame containing the strand information of the sliding windows. Windows can be obtained using the function getWinFromBamFile.
annotation a Grange object that you want to intersect with your windows. It can have mcols which contains the information or features that could be able to integrate to the input windows
getFeatureInfo whether to get the information of features in the mcols of annotation data or not. If FALSE the return windows will have an additional column indicating whether a window overlaps with any range of the annotion data. If TRUE the return windows will contain the information of features that overlap each window
overlapCol the columnn name of the return windows indicating whether a window overlaps with any range of the annotion data.
mcolsAnnot the column names of the mcols of the annotation data that you want to get information
collapse character which is used collapse multiple features that overlap with a same window into a string. If missing then we don't collapse them.
... used to pass parameters to GenomicRanges::findOverlaps

## Value

the input windows DataFrame with some additional columns

## See Also

getWinFromBamFile, plotHist, plotWin

## Examples

```
bamfilein = system.file('extdata','s2.sorted.bam',package = 'strandCheckR')
windows <- getWinFromBamFile(file = bamfilein)
#add chr before chromosome names to be consistent with the annotation
windows$Seq <- paste0('chr',windows$Seq)
library(TxDb.Hsapiens.UCSC.hg38.knownGene)
annot <- transcripts(TxDb.Hsapiens.UCSC.hg38.knownGene)
# get the transcript names that overlap with each window
windows <- intersectWithFeature(windows,annot,mcolsAnnot='tx_name')
# just want to know whether there's any transcript that
# overlaps with each window
windows <- intersectWithFeature(windows,annot,overlapCol='OverlapTranscript')
plotHist(windows,facets = 'OverlapTranscript')
plotWin(windows,facets = 'OverlapTranscript')
```

keptProbaWin
get the probability of begin kept for each window

## Description

calculate the keeping probability of each window based on its positive/negative proportion

## Usage

keptProbaWin(winPosAlignments, winNegAlignments, winWidth, winStep, threshold, pvalueThreshold, errorRate, mustKeepWin, minCov, maxCov, getWin, useCoverage = FALSE)

## Arguments

winPosAlignments
an object returned by getWinOfAlignments for positive reads
winNegAlignments an object returned by getWinOfAlignments for negative reads
winWidth the width of the sliding window, 1000 by default.
winStep the winStep length to sliding the window, 100 by default.
threshold the strand proportion threshold to test whether to keep a window or not.
pvalueThreshold
threshold of p-value
errorRate the probability that an RNA read takes the false strand. 0.01 by default
mustKeepWin the windows that must be kept regardless their strand proportion

| minCov | In the case that useCoverage=FALSE, if a window has least than minCov reads, <br> then it will be rejected regardless the strand proportion. For the case that useCoverage=TRUE, <br> if a window has max coverage least than minCov, then it will be rejected. 0 by <br> default |
| :--- | :--- |
| maxCov | In the case that useCoverage=FALSE, if a window has more than maxCov reads, <br> then it will be kept regardless the strand proportion. For the case that useCoverage=TRUE, <br> if a window has max coverage more than maxCov, then it will be kept. If 0 then <br> it doesn't have effect on selecting window. 0 by default. <br> if TRUE, the function will return a data frame containing the information of all |
| getWin $\quad$windows. It's FALSE by default. |  |
| useCoverage $\quad$if TRUE, then the strand information in each window corresponds to the sum <br> of coverage coming from positive/negative reads; and not the number of posi- <br> tive/negative reads as default. |  |

## Value

A list of 2 numeric-Rle objects containing keeping probability of each +/- alignments. If getWin=TRUE then the list contains an additional DataFrame for the number of reads and coverage of the input window $+/$ - alignments
keptReadFragment calculate the read fragments to be kept

## Description

calculate the keeping probability of each read fragment based on the keeping probability of the windows containing it. Then get the list of read fragments to be kept.

## Usage

keptReadFragment(fragments, keptProbaW)

## Arguments

| fragments | an IRange object defind the starting, ending position of each fragment |
| :--- | :--- |
| keptProbaW | an Rle object define the kept probability of each sliding window |

## Value

an integer vector of read fragment indices to be kept

```
plotHist Plot the histogram of positive proportions
```

## Description

Plot the histogram of positive proportions of the input histogram data frame

## Usage

```
plotHist(windows, save = FALSE, file = "hist.pdf", group_by = NULL,
normalize_by = NULL, split = c(10, 100, 1000), breaks = 100,
useCoverage = FALSE, heatmap = FALSE, ...)
```

## Arguments

| windows | data frame containing the strand information of the sliding windows. Windows <br> can be obtained using the function getWinFromBamFile. <br> if TRUE, then the plot will be save into the file given by file parameter |
| :--- | :--- |
| save | the file name to save to plot <br> file <br> group_by |
| the column names of windows that will be used to group the data |  |
| normalize_by | the column names of windows that will be used to normalize the read count or <br> read coverage into proportion <br> an integer vector that specifies how you want to partition the windows based <br> on the coverage. By default split = c(10,100,1000), which means that your <br> windows will be partitionned into 4 groups, those have coverage < 10, from 10 <br> to 100, from 100 to 1000, and > 1000 |
| split | an integer giving the number of bins for the histogram <br> if TRUE then plot the coverage strand information, otherwise plot the number <br> of reads strand information. FALSE by default |
| breaks |  |
| useCoverage |  |
| if TRUE, then use heat map to plot the histogram, otherwise use barplot. FALSE |  |

## Value

If heatmap=FALSE: a ggplot object

## See Also

getWinFromBamFile, plotWin

## Examples

```
bamfilein = system.file('extdata','s1.sorted.bam',package = 'strandCheckR')
win <- getWinFromBamFile(file = bamfilein,sequences='10')
plotHist(win)
```

```
plotWin Plot the Proportion of + Stranded Reads
```

## Description

Plot the number of reads vs the proportion of ' + ' stranded reads.

## Usage

plotWin(windows, split = c(10, 100, 1000), threshold = c(0.6, 0.7, 0.8, $0.9)$, save = FALSE, file = "win.pdf", group_by = NULL, useCoverage = FALSE, ...)

## Arguments

windows data frame containing the strand information of the sliding windows. Windows should be obtained using the function getWinFromBamFile to ensure the correct data structure.
split an integer vector that specifies how you want to partition the windows based on coverage. By default split $=c(10,100,1000)$, partition windows into 4 groups based on these values.
threshold a numeric vector between $0.5 \& 1$ that specifies which threshold lines to draw on the plot. The positive windows above the threshold line (or negative windows below the threshold line) will be kept when using filterDNA.
save if TRUE, then the plot will be save into the file given by file parameter
file the file name to save to plot
group_by colnames of windows which will be used to split the plot
useCoverage if TRUE then plot the coverage strand information, otherwise plot the number of reads strand information. FALSE by default
... used to pass parameters to facet_wrap during plotting

## Details

This function will plot the proportion of ' + ' stranded reads for each window, against the number of reads in each window. The threshold lines indicate the hypothetical boundary where windows will contain reads to kept or discarded using the filtering methods of filterDNA. Any plot can be easily modified using standard ggplot2 syntax (see Examples)

## Value

The plot will be returned as a standard ggplot2 object

## See Also

getWinFromBamFile, plotHist

## Examples

```
bamfilein = system.file('extdata','s2.sorted.bam',package = 'strandCheckR')
windows <- getWinFromBamFile(file = bamfilein,sequences = '10')
plotWin(windows)
# Change point colour using ggplot2
library(ggplot2)
plotWin(windows) +
scale_colour_manual(values = rgb(seq(0, 1, length.out = 4), 0, 0))
```

```
summarizeHist
```

Summarize the histogram of strand proportions from the input windows data frame

## Description

Summarize the histogram of positive proportions from the input windows obtained from the function getWinFromBamFile

## Usage

summarizeHist(windows, split $=c(10,100,1000)$, breaks $=100$, useCoverage = FALSE, group_by = NULL, normalize_by = NULL)

## Arguments

windows data frame containing the strand information of the sliding windows. Windows can be obtained using the function getWinFromBamFile.
split an integer vector that specifies how you want to partition the windows based on the coverage. By default split $=c(10,100,1000)$, which means that your windows will be partitionned into 4 groups, those have coverage $<10$, from 10 to 100 , from 100 to 1000 , and $>1000$
breaks an integer giving the number of bins for the histogram
useCoverage if TRUE then plot the coverage strand information, otherwise plot the number of reads strand information. FALSE by default
group_by the column names of windows that will be used to group the data
normalize_by the column names of windows that will be used to normalize the read count or read coverage into proportion

## Value

a dataframe object

## See Also
