1 Introduction

Sushi is an R package for plotting genomic data stored in multiple common genomic formats including bed, bedpe, bedgraph format. The package was designed to be very flexible to allow for combinations of plots into multipanel figures that can include plots made by Sushi, R basecode, or other R packages. Sushi allows for simple flexible plotting of gene structures, transcript structures, sequencing tracks, ChIP-seq peaks, chromatin interactions, GWAS results and other common genomic data types. This vignette shows some examples of the functions included in Sushi to get you started with plotting these diverse data types.

2 Data

2.1 Data types

Sushi accepts 4 types of genomic data as input. These include:

- bed format: 3-6 columns (chromosome, start, stop, name, score, strand)
- bedpe format: 6-10 columns (chromosome1, start1, stop1, chromosome2, start2, stop2, name, score, strand1, strand2)
- bedgraph format: 4 columns (chromosome, start, stop, score)
- interaction matrix: This is matrix in which row and column names are genomic coordinates and matrix values are some type of interaction score.

** strands can be represented as 1 or -1 or "+" and "-".

** Some functions may require additional information depending on the plot and features desired.

2.2 Example datasets

To illustrate how Sushi works, we have included several publicly available data sets in the package Sushi. The data types include RNA-seq, ChIP-seq, ChIA-PET, and HiC data:

Sushi_5C.bedpe	Sanyal et al. [7]
Sushi_ChIAPET_pol2.bedpe	Li et al. [4]
Sushi_ChIPExo_CTCF.bedgraph	Rhee and Pugh [6]
Sushi_ChIPSeq_CTCF.bedgraph	The ENCODE Project Consortium [8]
Sushi_ChIPSeq_pol2.bed	The ENCODE Project Consortium [8]
Sushi_ChIPSeq_pol2.bedgraph	The ENCODE Project Consortium [8]
Sushi_ChIPSeq_severalfactors.bed	The ENCODE Project Consortium [8]
Sushi_DNaseI.bedgraph	Neph et al. [5]
Sushi_GWAS.bed	International Consortium for Blood Pressure [3]
Sushi_HiC.matrix	Dixon et al. [2]
Sushi_RNASeq_K562.bedgraph	The ENCODE Project Consortium [8]
Sushi_genes.bed	Biomart [1]
Sushi_hg18_genome	Biomart [1]
Sushi_transcripts.bed	The ENCODE Project Consortium [8]

These data sets can be loaded using the following commands:

```
> library('Sushi')
> Sushi_data = data(package = 'Sushi')
> data(list = Sushi_data$results[,3])
```

To see which data sets are loaded

```
> Sushi_data$results[,3]

[1] "Sushi_5C.bedpe" "Sushi_ChIAPET_pol2.bedpe"
[3] "Sushi_ChIPExo_CTCF.bedgraph" "Sushi_ChIPSeq_CTCF.bedgraph"
[5] "Sushi_ChIPSeq_pol2.bed" "Sushi_ChIPSeq_pol2.bedgraph"
[7] "Sushi_ChIPSeq_severalfactors.bed" "Sushi_DNaseI.bedgraph"
[9] "Sushi_GWAS.bed" "Sushi_HiC.matrix"
[11] "Sushi_RNASeq_K562.bedgraph" "Sushi_genes.bed"
[13] "Sushi_hg18_genome" "Sushi_transcripts.bed"
```

3 Functions

3.1 Functions overview

Sushi functions can be broken down into 3 categories: plotting, annotating, zooming, and coloring. Plotting functions generate a basic plot object using the data. Annotating functions add information to the plots such as an x-axis labeling the genomic region or a legend describing the values represented by different colors. Zooming functions allow for highlighting and zooming of genomic regions, which are of particular use for multipanel plots generated with base R functions `mfrow()` or `layout()`. The coloring functions provide simple tools for generating R colors and palettes.

- Plotting functions: `plotBed()`, `plotBedgraph()`, `plotBedpe()`, `plotGenes()`, `plotHiC()`, and `plotManhattan()`
- Annotating functions: `labelgenome()` and `addlegend()`
- Zooming functions: `zoomsregion()` and `zoombox()`
- Coloring functions: `maptocolors()`, `SushiColors()`, and `opaque()`

3.2 Non-Sushi Functions

An important characteristic of Sushi plots is their compatibility with all base R functions and their ability to be combined into complex multipanel figures. Two of the most useful base R functions for creating multipanel figures are `layout()` and `mfrow()`. Basic R plotting functions such as `axis()`, `mtext()`, and `legend()` are also particularly well suited to combine with Sushi plots. A familiarity with these functions will greatly improve your ability to create Sushi plots.

3.3 `plotBedgraph`

Signal tracks can be plotted using `plotBedgraph()`. The input requires data in bedgraph format. We will demonstrate this using bedgraph data representing a DNaseI hypersensitivity experiment in K562 cells.

```
> head(Sushi_DNaseI.bedgraph)
```

	chrom	start	end	value
1	chr11	1640504	1640664	1
2	chr11	1640904	1641004	1
3	chr11	1641004	1641064	2
4	chr11	1641064	1641164	1
5	chr11	1645224	1645384	1
6	chr11	1645504	1645664	1

The `plotBedgraph()` function is used to plot the data. As with most Sushi functions the basic required arguments include the data to be plotted, the chromosome, and a start and stop position.

```
> chrom          = "chr11"
> chromstart     = 1650000
> chromend       = 2350000
> plotBedgraph(Sushi_DNaseI.bedgraph, chrom, chromstart, chromend, colorbycol= SushiColors(5))
```

To annotate the genome position we use the `labelgenome()` function. We use `n = 4` to specify the desired number of tickmarks. The scale is set to `Mb` (other options are `Kb` or `bp`).

```
> labelgenome(chrom,chromstart,chromend,n=4,scale="Mb")
```

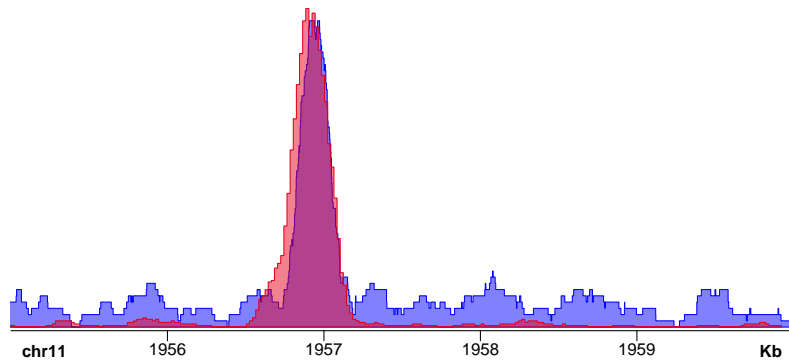

The y-axis can be added using basic R functions `mtext()` and `axis()`.

```
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> axis(side=2,las=2,tcl=.2)
```

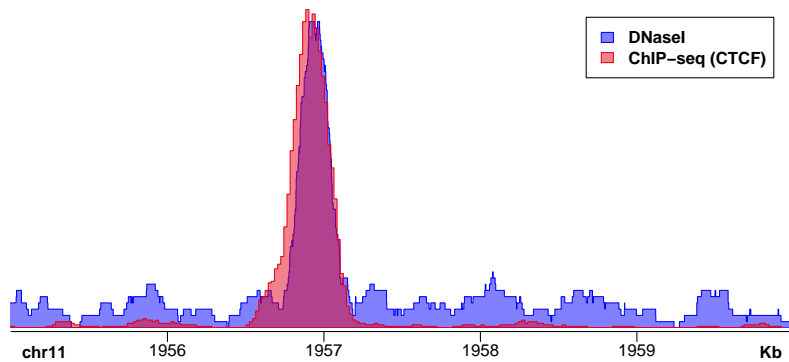

Multiple bedgraph tracks can be plotted on the same plot by setting `overlay=TRUE`. Transparencies can be added for easier viewing by adjusting the transparency value. The second plot can be rescaled to the maximum of the first plot by setting `rescaleoverlay=TRUE`.

```
> chrom          = "chr11"
> chromstart     = 1955000
> chromend       = 1960000
> plotBedgraph(Sushi_ChIPSeq_CTCF.bedgraph,chrom,chromstart,chromend,
               transparency=.50,color=SushiColors(2)(2)[1])
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom,chromstart,chromend,
               transparency=.50,color=SushiColors(2)(2)[2],overlay=TRUE,
               rescaleoverlay=TRUE)
> labelgenome(chrom,chromstart,chromend,n=3,scale="Kb")
```

Then we can use the base R function `legend()` to add a legend to the plot. First we need to use the `rgb` function to add transparency to the colors in order to match our plot.

```
> legend("topright",inset=0.025,legend=c("DNaseI", "ChIP-seq (CTCF)"),
      fill=opaque(SushiColors(2)(2)),border=SushiColors(2)(2),text.font=2,
      cex=1.0)
```

Setting `flip=TRUE` is another method that can be used to compare tracks. First, we will use `mflow` to divide the plotting device into two vertically stacked regions.

```
> par(mfrow=c(2,1),mar=c(1,4,1,1))
```

Next, we plot the first plot. We set the transparency of the plot to 0.5. We will also add the legend.

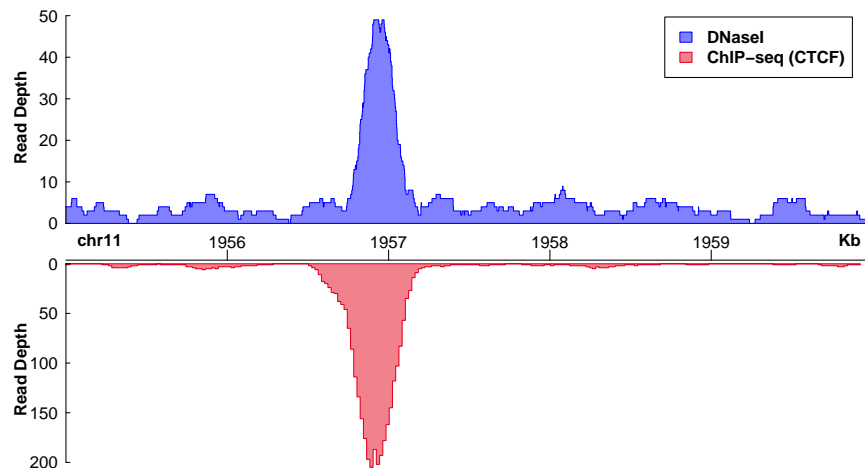

```
> plotBedgraph(Sushi_ChIPSeq_CTCF.bedgraph,chrom,chromstart,chromend,transparency=.50,
               color=SushiColors(2)(2)[1])
> axis(side=2,las=2,tcl=.2)
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> legend("topright",inset=0.025,legend=c("DNaseI","ChIP-seq (CTCF)"),
        fill=opaque(SushiColors(2)(2)),border=SushiColors(2)(2),text.font=2,
        cex=1.0)
```

Finally, we add the second plot with `flip=TRUE`. We will also label the x-axis using `labelgenome()` and label the y-axis using `mtext()` and `axis()`.

```
> plotBedgraph(Sushi_DNaseI.bedgraph, chrom, chromstart, chromend,
               transparency=.50, flip=TRUE, color=SushiColors(2)(2)[2])
> labelgenome(chrom,chromstart,chromend,side=3,n=3,scale="Kb")
```

```
> axis(side=2,las=2,tcl=.2,at=pretty(par("yaxp")[c(1,2)]),
      labels=-1*pretty(par("yaxp")[c(1,2)]))
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
```

3.4 plotHic

HiC interaction plots can be plotted given an interaction matrix in which row and column names are genomic coordinates and matrix values are some tye of interaction score.

```
> Sushi_HiC.matrix[100:105,100:105]

      4460000  4500000  4540000  4580000  4620000  4660000
4460000  60.758775  18.84723  33.31506  22.56641   7.926361  10.69235
4500000  18.847231  32.56282  36.31212  29.04343  13.375643  12.67360
4540000  33.315060  36.31212  17.97024  43.43753  20.411952  16.98875
4580000  22.566409  29.04343  43.43753  38.93754  25.206417  23.87764
4620000   7.926361  13.37564  20.41195  25.20642   9.201501  38.33665
4660000  10.692351  12.67360  16.98875  23.87764  38.336646  22.55054
```

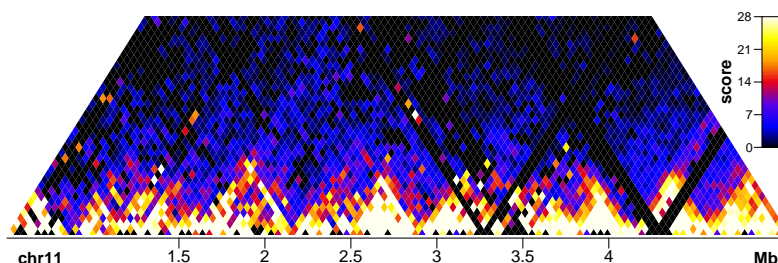

The `plotHic()` function is used to plot the data while the `labelgenome()` function is used to add the genome labels to the x-axis. `plotHic()` returns an object indicating the color palette and data range that can be fed into `addlegend()` to create a legend.

```
> chrom          = "chr11"
> chromstart     = 500000
> chromend       = 5050000
> phic = plotHic(Sushi_HiC.matrix, chrom,chromstart, chromend, max_y = 20,
                zrange=c(0,28), palette=SushiColors(7))
```

```

> addlegend(phic[[1]], palette=phic[[2]], title="score", side="right",
            bottominset=0.4, topinset=0, xoffset=-.035, labelside="left",
            width=0.025, title.offset=0.035)
> labelgenome(chrom, chromstart, chromend, n=4, scale="Mb",
              edgeblankfraction=0.20)

```

plotHic() has a number of customizable options. The plot can be flipped over the x-axis by setting `flip = TRUE`. The color palette can be changed by the `palette` argument.

addlegend() also has customizable features. The legend can be moved to the left side of the plot by setting `side = "left"` and the labeling can be moved to the right side of the legend by setting `labelside = "right"`. The vertical position of the legend can be adjusted by changing the `topinset` and `bottominset`.

Finally, the x-axis label can be moved to the top of the plot by setting `side = 3` in the `labelgenome()` function.

```

> chrom          = "chr11"
> chromstart     = 500000
> chromend       = 5050000
> phic = plotHic(Sushi_HiC.matrix, chrom, chromstart, chromend, max_y = 20,
                xrange=c(0,28), flip=TRUE, palette=topo.colors)
> addlegend(phic[[1]], palette=phic[[2]], title="score", side="left", bottominset=0.1,
            topinset=0.5, xoffset=-.035, labelside="right", width=0.025, title.offset=0.035)
> labelgenome(chrom, chromstart, chromend, side=3, n=4, scale="Mb", edgeblankfraction=0.20)

```

3.5 plotBedpe

`plotBedpe()` allows for data in bedpe format to be plotted in multiple fashions. To illustrate this we will use 5C data formatted in the following way.

```
> head(Sushi_5C.bedpe)
```

	chrom1	start1	end1	chrom2	start2	end2	name	score	strand1
1	chr2	234208447	234223064	chr2	234156762	234159135	NA	44.39862	.
2	chr15	41711734	41718116	chr15	41802421	41808201	NA	20.62534	.
3	chr11	64172456	64183193	chr11	64068878	64079209	NA	16.91630	.
4	chr2	234208447	234223064	chr2	234163674	234170252	NA	12.34501	.
5	chr6	41755186	41769245	chr6	41435903	41452283	NA	11.63480	.
6	chr11	64159283	64172456	chr11	64068878	64079209	NA	11.13098	.

	strand2	samplenum
1	.	1
2	.	1
3	.	1
4	.	1
5	.	1
6	.	1

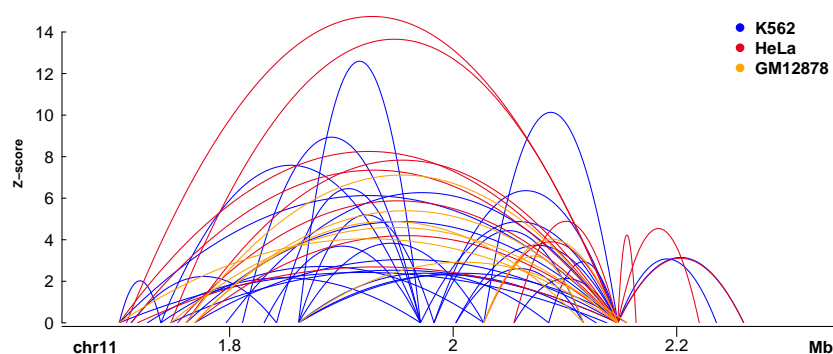

`plotBedpe()` can plot bedpe as arches. The height, linewidth, and color of each arch can be scaled to represent different aspects of the data. Here the height of the arches represents the Z-score of the 5C interaction, the color represents the cell line each interaction was detected in, and the line widths are kept constant (default `lwd = 1`).

```
> chrom          = "chr11"
> chromstart     = 1650000
> chromend       = 2350000
> pbpe = plotBedpe(Sushi_5C.bedpe, chrom, chromstart, chromend,
                   heights = Sushi_5C.bedpe$score, plotype="loops",
```

```

        colorby=Sushi_5C.bedpe$samplenumbers,
        colorbycol=SushiColors(3))
> labelgenome(chrom, chromstart,chromend,n=3,scale="Mb")
> legend("topright",inset =0.01,legend=c("K562","HeLa","GM12878"),
        col=SushiColors(3)(3),pch=19,bty='n',text.font=2)
> axis(side=2,las=2,tcl=.2)
> mtext("Z-score",side=2,line=1.75,cex=.75,font=2)

```

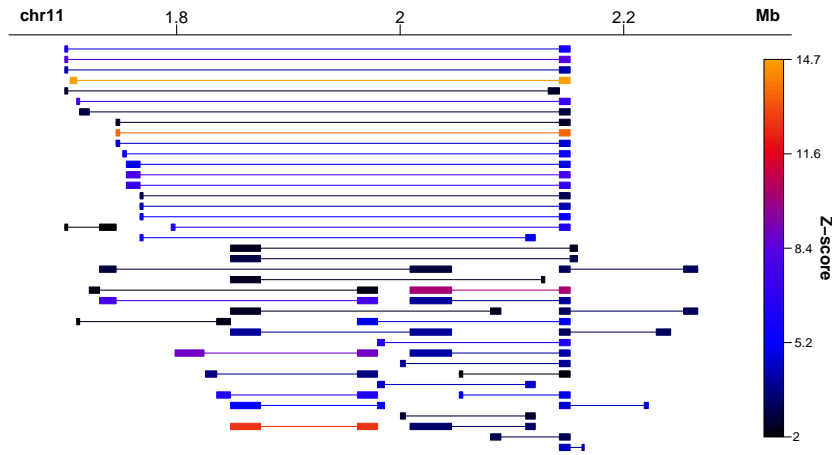

The plot can be flipped over the x-axis by setting `flip = TRUE`, Bedpe elements can be represented by boxes and straight lines by setting `plottype = "lines"`. And colors can be used to represent Z-scores by setting `colorby = "Sushi_5C.bedpe$score"`.

```

> chrom          = "chr11"
> chromstart     = 1650000
> chromend       = 2350000
> pbpe = plotBedpe(Sushi_5C.bedpe,chrom,chromstart,chromend,flip=TRUE,
                  plottype="lines",colorby=Sushi_5C.bedpe$score,
                  colorbycol=SushiColors(5))
> labelgenome(chrom, chromstart,chromend,side=3,n=3,scale="Mb")
> addlegend(pbpe[[1]],palette=pbpe[[2]],title="Z-score",side="right",bottominset=0.05,
            topinset=0.05,xoffset=-.035,labelfont="right",width=0.025,title.offset=0.045)

```

3.6 plotBed

plotBed provides multiple different ways to represent genomic data stored in bed format. Below are the first six lines of a bed file detailing reads from Pol2 ChIP-Seq analysis of K562 cells.

```
> head(Sushi_ChIPSeq_pol2.bed)
```

	chrom	start	end	name	score	strand
1	chr11	2280543	2280570	GGGCTCTCTCCGGCTTCCCTGTCCCGT	63	-1
2	chr11	2288946	2288973	CCTTCCCATCCGCAGGGGCACACATG	1000	-1
3	chr11	2272471	2272498	TGGGCATCAGTCAGGCTCCTTCCCCAG	1000	-1
4	chr11	2288939	2288966	ATCCGCAGGGGCACACATGAGTCACC	1000	-1
5	chr11	2281534	2281561	TGTCCTAGTGACAAGTGGCCGACTTG	250	-1
6	chr11	2286805	2286832	GGTGAGGGCCAGCAGCTCCCTGGGGGG	250	1

Leaving row set to auto provides a pile-sup style plot. Here the colorby argument is used to color the bed elements by the strand.

```
> chrom = "chr11"
> chromstart = 2281200
> chromend = 2282200
> plotBed(beddata = Sushi_ChIPSeq_pol2.bed, chrom = chrom, chromstart = chromstart,
          chromend = chromend, colorby = Sushi_ChIPSeq_pol2.bed$strand,
          colorbycol = SushiColors(2), row = "auto", wiggle=0.001)
> labelgenome(chrom, chromstart, chromend, n=2, scale="Kb")
> legend("topright", inset=0, legend=c("reverse", "forward"), fill=SushiColors(2)(2),
        border=SushiColors(2)(2), text.font=2, cex=0.75)
```

Setting `splitstrand = TRUE` plots reads from different strands in two separate vertical regions.

```
> chrom          = "chr11"
> chromstart     = 2281200
> chromend       = 2282200
> plotBed(beddata = Sushi_ChIPSeq_pol2.bed, chrom = chrom, chromstart = chromstart,
          chromend = chromend, colorby = Sushi_ChIPSeq_pol2.bed$strand,
          colorbycol = SushiColors(2), row = "auto", wiggle=0.001, splitstrand=TRUE)
> labelgenome(chrom, chromstart, chromend, n=2, scale="Kb")
> legend("topright", inset=0, legend=c("reverse", "forward"), fill=SushiColors(2)(2),
        border=SushiColors(2)(2), text.font=2, cex=0.75)
```

`plotBed` can also plot bed elements on different rows as specified by the user. First, we will use the Sushi function `maptocolors()` to assign a different color to each row.

```
> Sushi_ChIPSeq_severalfactors.bed$color =
  maptocolors(Sushi_ChIPSeq_severalfactors.bed$row,
              col=SushiColors(6))
```

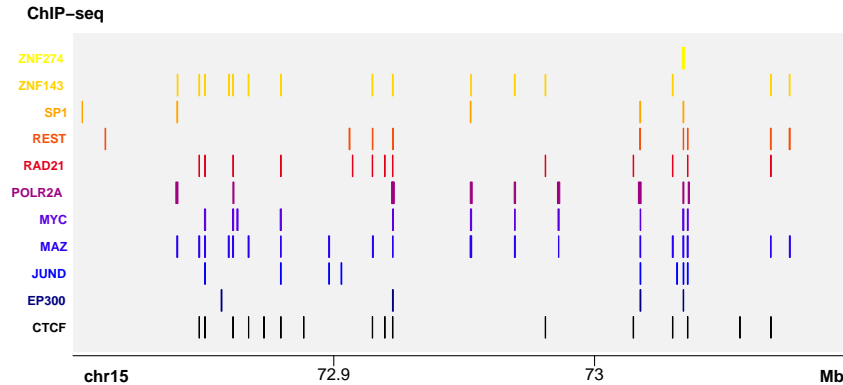

By providing row and color information `plotBed()` can be used to compare bed elements from different samples by plotting them on different rows.

```
> chrom          = "chr15"
> chromstart     = 72800000
> chromend       = 73100000
> plotBed(beddata = Sushi_ChIPSeq_severalfactors.bed, chrom = chrom,
          chromstart = chromstart, chromend = chromend,
          rownumber = Sushi_ChIPSeq_severalfactors.bed$row, type = "circles",
          color=Sushi_ChIPSeq_severalfactors.bed$color, row="given",
          plotbg="grey95", rowlabels=unique(Sushi_ChIPSeq_severalfactors.bed$name),
          rowlabelcol=unique(Sushi_ChIPSeq_severalfactors.bed$color), rowlabelcex=0.75)
> labelgenome(chrom, chromstart, chromend, n=3, scale="Mb")
> mtext("ChIP-seq", side=3, adj=-0.065, line=0.5, font=2)
```

That same data can be represented by rectangles that depict the actual width of each bed element.

```
> plotBed(beddata = Sushi_ChIPSeq_severalfactors.bed, chrom = chrom,
          chromstart = chromstart, chromend = chromend,
          rownumber = Sushi_ChIPSeq_severalfactors.bed$row, type = "region",
          color=Sushi_ChIPSeq_severalfactors.bed$color, row="given",
          plotbg="grey95", rowlabels=unique(Sushi_ChIPSeq_severalfactors.bed$name),
          rowlabelcol=unique(Sushi_ChIPSeq_severalfactors.bed$color), rowlabelcex=0.75)
> labelgenome(chrom, chromstart, chromend, n=3, scale="Mb")
> mtext("ChIP-seq", side=3, adj=-0.065, line=0.5, font=2)
```

`plotBed()` can also be used to plot heatmaps representing the density of bed elements. First, we will use the `biomaRt` function `getBM()` to get the gene information we require.

```
> chrom          = "chr15"
> chromstart     = 60000000
> chromend       = 80000000
> chrom_biomart   = gsub("chr", "", chrom)
> mart=useMart(host='may2009.archive.ensembl.org', biomart='ENSEMBL_MART_ENSEMBL',
               dataset='hsapiens_gene_ensembl')
> geneinfobed = getBM(attributes = c("chromosome_name", "start_position", "end_position"),
                      filters= c("chromosome_name", "start", "end"),
                      values=list(chrom_biomart, chromstart, chromend), mart=mart)
> geneinfobed[,1] = paste("chr", geneinfobed[,1], sep="")
```

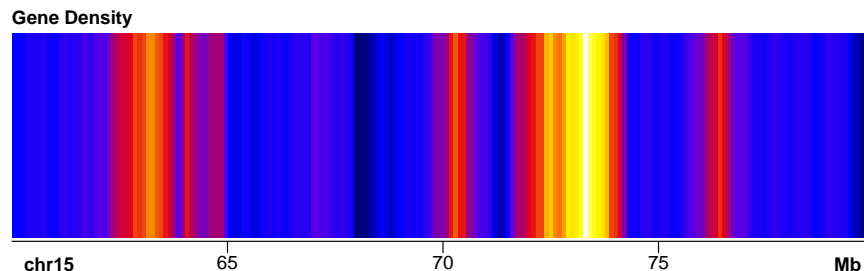

The data is in simple bed format with just three columns representing chromosome, start, and stop.

```
> head (geneinfobed)

  chromosome_name start_position end_position
1          chr15      73372069      73372334
2          chr15      64580642      64580710
3          chr15      63375442      63375557
4          chr15      72570353      72570422
5          chr15      60903209      60903293
6          chr15      70130646      70130724
```

Now we can make a gene density plot using the `plotBed` function.

```
> plotBed(beddata = geneinfobed[!duplicated(geneinfobed),],chrom = chrom,
          chromstart = chromstart,chromend =chromend,row='supplied',
          palettes = list(SushiColors(7)), type = "density")
> labelgenome(chrom, chromstart, chromend, n=4,scale="Mb",edgeblankfraction=0.10)
> mtext("Gene Density",side=3, adj=0,line=0.20,font=2)
```

3.7 plotManhattan

`plotManhattan()` differs from most other Sushi functions in that it can plot multiple chromosomes in a single plot. Because of this `plotManhattan` requires some additional inputs. It requires an object in bed format describing the location of data points as well as vector of p-values (typically one of the columns of the bed file). But it also requires an genome object that describes which chromosomes to plot and their sizes (in bp). The genome object is very similar to the genome files used for `bedtools`.

The bed data should look something like this:

```
> head(Sushi_GWAS.bed)

chr.hg18 pos.hg18 pos.hg18.1      rsid pval.GC.DBP V6
1   chr1  1695996   1695996   rs6603811    0.003110 .
2   chr1  1696020   1696020   rs7531583    0.000824 .
3   chr1  1698661   1698661   rs12044597   0.001280 .
4   chr1  1711339   1711339   rs2272908    0.001510 .
5   chr1  1712792   1712792   rs3737628    0.001490 .
6   chr1  1736016   1736016   rs12408690   0.004000 .
```

And the genome file should look like this:

```
> head(Sushi_hg18_genome)

      V1      V2
1 chr1 247249719
2 chr10 135374737
```

```

3 chr11 134452384
4 chr12 132349534
5 chr13 114142980
6 chr14 106368585

```

The `plotManhattan()` function is used to plot the data while the `labelgenome()` function is used to add the genome labels to the x-axis. The `labelgenome()` function also requires a genome object.

```

> plotManhattan(bedfile=Sushi_GWAS.bed,pvalues=Sushi_GWAS.bed[,5],
               col=SushiColors(6),genome=Sushi_hg18_genome,cex=0.75)
> labelgenome(genome=Sushi_hg18_genome,n=4,scale="Mb",
             edgeblankfraction=0.20,cex.axis=.5)
> axis(side=2,las=2,tcl=.2)
> mtext("log10(P)",side=2,line=1.75,cex=1,font=2)
> mtext("chromosome",side=1,line=1.75,cex=1,font=2)

```

pdf
2

3.8 plotGenes

`plotGenes()` can be used to plot gene structures that are stored in bed format. If no `geneinfo` object is provided genes are looked up in the region using biomart with `biomart='ensembl'` and `dataset='hsapiens_gene_ensembl'`.

```
> head(Sushi_genes.bed)
```

	chrom	start	stop	gene	score	strand
1	chr15	73017309	73017438	COX5A	.	-1
2	chr15	72999672	72999836	COX5A	.	-1
3	chr15	73003042	73003164	COX5A	.	-1
4	chr15	73006160	73006281	COX5A	.	-1
5	chr15	73008510	73008626	COX5A	.	-1

Using `plotGenes()` with arguments `bentline=FALSE` and `plotgenetype="arrow"` produces arrow and line gene structures.

```
> chrom          = "chr15"
> chromstart     = 72998000
> chromend       = 73020000
> pg = plotGenes(Sushi_genes.bed, chrom, chromstart, chromend ,
                 types=Sushi_genes.bed$type, maxrows=1, bheight=0.2,
                 plotgenetype="arrow", bentline=FALSE,
                 labeloffset=.4, fontsize=1.2, arrowlength = 0.025,
                 labeltext=TRUE)
> labelgenome( chrom, chromstart, chromend, n=3, scale="Mb")
```

This function can also be used to plot transcript structures. The first 20 lines of a data frame describing RNA seq data are shown below.

```
> Sushi_transcripts.bed[1:20,]
```

	chrom	start	stop	gene	score	strand	type
1	chr15	73062668	73062770	ENST000000362710	0.000000	-1	exon

15	chr15	72972532	72972714	ENST00000379693	2.422616	1	exon
16	chr15	72972055	72972196	ENST00000379693	2.422616	1	exon
17	chr15	72970773	72970973	ENST00000379693	2.422616	1	exon
18	chr15	72969965	72970048	ENST00000379693	2.422616	1	exon
19	chr15	72972532	72972714	ENST00000352410	0.917141	1	exon
20	chr15	72972055	72972196	ENST00000352410	0.917141	1	exon

A vector type can be used to specify if each region is an 'exon' or 'utr' while `plotgenetype="box"` plots regions as a boxes rather than arrows. The data can be plotted using `plotGenes()`. The `colorby` argument is used to color the transcripts by $\log_{10}(\text{FPKM})$. UTR regions are drawn as shorter boxes than exons.

```
> chrom = "chr15"
> chromstart = 72965000
> chromend = 72990000
> pg = plotGenes(Sushi_transcripts.bed, chrom, chromstart, chromend ,
  types = Sushi_transcripts.bed$type,
  colorby=log10(Sushi_transcripts.bed$score+0.001),
  colorbycol= SushiColors(5), colorbyrange=c(0,1.0),
  labeltext=TRUE, maxrows=50, height=0.4, plotgenetype="box")
> labelgenome( chrom, chromstart, chromend, n=3, scale="Mb")
> addlegend(pg[[1]], palette=pg[[2]], title="log10(FPKM)", side="right",
  bottominset=0.4, topinset=0, xoffset=-.035, labelside="left",
  width=0.025, title.offset=0.055)
```

3.9 Zoom functions

A critical characteristic of the Sushi package is its ability to create highly customizable, publication-ready, multi-panel figures. Here, we will create a basic three panel figure and demonstrate how the zoom functions work (`zoomsregion` and `zoombox`). To illustrate these feature we will use the `plotBedgraph()` function to plot bedgraph data representing a DNaseI hypersensitivity experiment in K562 cells.

In order to make a multipanel figure we will use the R function `layout`. `Layout` divides the device into rows and columns according to a matrix you provide. The matrix also tells it which plots will appear on which parts of the plotting device. Below we make a 2 by 2 matrix. The entire top row will be used to plot the first plot while the bottom row will contain two plots. For more info on `layout` try `?layout`.

```
> layout(matrix(c(1,1,2,3),2, 2, byrow = TRUE))
> par(mar=c(3,4,1,1))
```

Next we will add the first plot

```
> chrom          = "chr11"
> chromstart     = 1900000
> chromend       = 2350000
```

```

> plotBedgraph(Sushi_DNaseI.bedgraph,chrom,chromstart=chromstart,
               chromend=chromend,colorbycol= SushiColors(5))
> labelgenome(chrom,chromstart=chromstart,chromend=chromend,n=4,
               scale="Mb")
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> axis(side=2,las=2,tcl=.2)

```

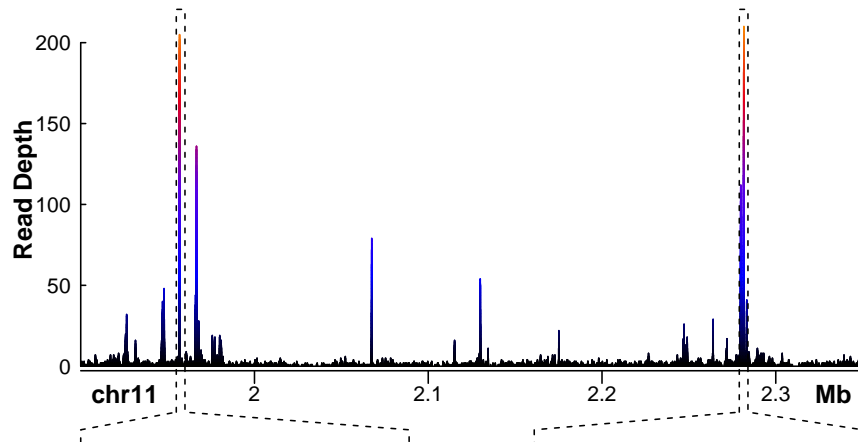

Next we will add the zoom regions using the function `zoomsregion()`. The argument `offsets` is used to precisely position the left and right edges of the widest part of the zoom.

```

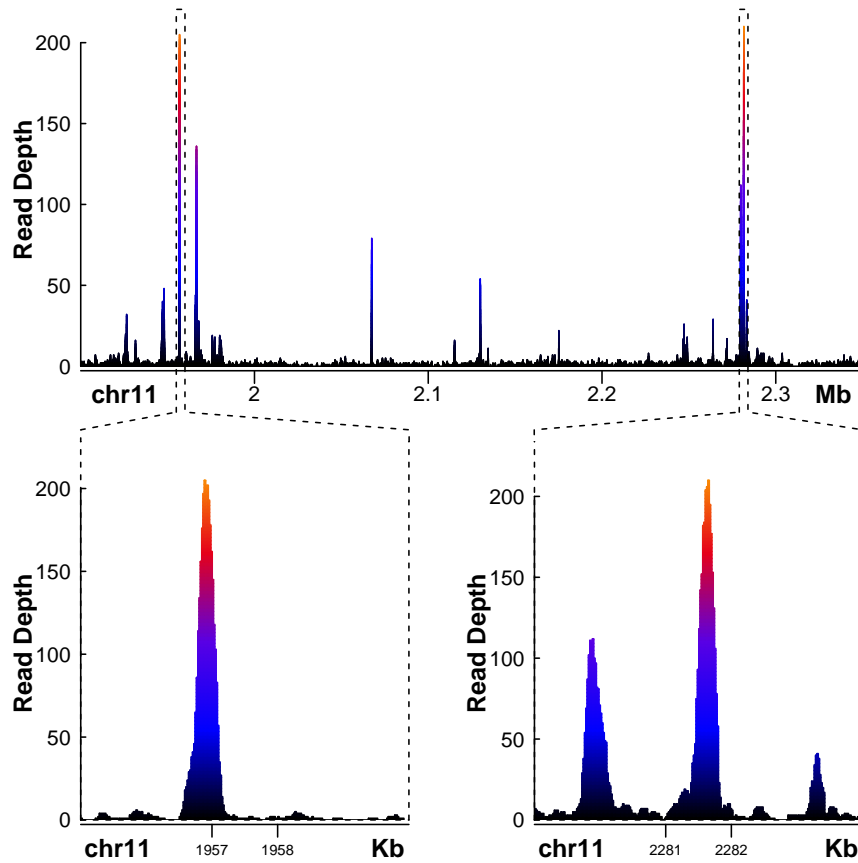

> zoomregion1      = c(1955000,1960000)
> zoomregion2      = c(2279000,2284000)
> zoomsregion(zoomregion1,extend=c(0.01,0.13),wideextend=0.05,
               offsets=c(0,0.580))
> zoomsregion(zoomregion2,extend=c(0.01,0.13),wideextend=0.05,
               offsets=c(0.580,0))

```

Then we can add each of the zoomed inset regions. For, each region we need execute the `zoombox` function in order to draw the lines around the new plots.

```
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom,chromstart=zoomregion1[1],
  chromend=zoomregion1[2],colorbycol= SushiColors(5))
> labelgenome(chrom,chromstart=zoomregion1[1],chromend=zoomregion1[2],
  n=4,scale="Kb",edgeblankfraction=0.2,cex.axis=.75)
> zoombox()
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> axis(side=2,las=2,tcl=.2)
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom,chromstart=zoomregion2[1],
  chromend=zoomregion2[2],colorbycol= SushiColors(5))
> labelgenome(chrom,chromstart=zoomregion2[1],chromend=zoomregion2[2],
  n=4,scale="Kb",edgeblankfraction=0.2,cex.axis=.75)
> zoombox()
> mtext("Read Depth",side=2,line=1.75,cex=1,font=2)
> axis(side=2,las=2,tcl=.2)
```

3.10 Color functions

Sushi includes three functions to assist in the generating of R colors and color palettes: `SushiColors()`, `maptocolors()`, `opaque()`.

3.10.1 SushiColors

`SushiColors()` provides default color palettes for the Sushi package.

To see a list of available color palettes:

```
> SushiColors(palette='list')
```

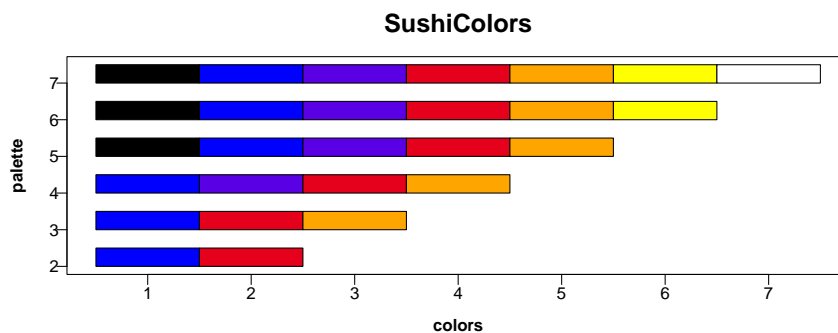

```
[1] 2 3 4 5 6 7
```

To view the color palettes:

```

> plot(1,xlab='',xaxt='n',ylab='',yaxt='n',xlim=c(0.5,7.5),
      ylim=c(2,7.5),type='n')
> for (i in (2:7))
{
  for (j in (1:i))
  {
    rect(j-.5,i,j+.5,i+.5,col=SushiColors(i)(i)[j])
  }
}
> axis(side=2,at=(2:7),labels=(2:7),las=2)
> axis(side=1,at=(1:7),labels=(1:7))
> mtext("SushiColors",side=3,font=2, line=1, cex=1.5)
> mtext("colors",side=1,font=2, line=2)
> mtext("palette",side=2,font=2, line=2)

```

3.10.2 opaque

`opaque()` takes any color or vector of colors and makes them opaque. The degree of transparency is determined by the argument `transparency` which is a value between 0 and 1.

```

> plot(1,xlab='',xaxt='n',ylab='',yaxt='n',bty='n',type='n',
      xlim=c(-.15,1.05),ylim=c(-1,2))
> for (i in seq(0,1,by=0.1))
{
  rect(i-.05,-1,i+.05,1,col=opaque("red",transparency=i))
  rect(i-.05,0,i+.05,2,col=opaque("blue",transparency=1-i))
}
> axis(side=1,at=seq(0,1,by=0.1),labels=seq(0,1,by=0.1))
> mtext("red transparency",side=1,font=2, line=2)
> axis(side=3,at=seq(0,1,by=0.1),labels=seq(1,0,by=-0.1))
> mtext("blue transparency",side=3,font=2, line=2)
> text(-0.075,1.5,labels="blue",font=2,adj=1)

```

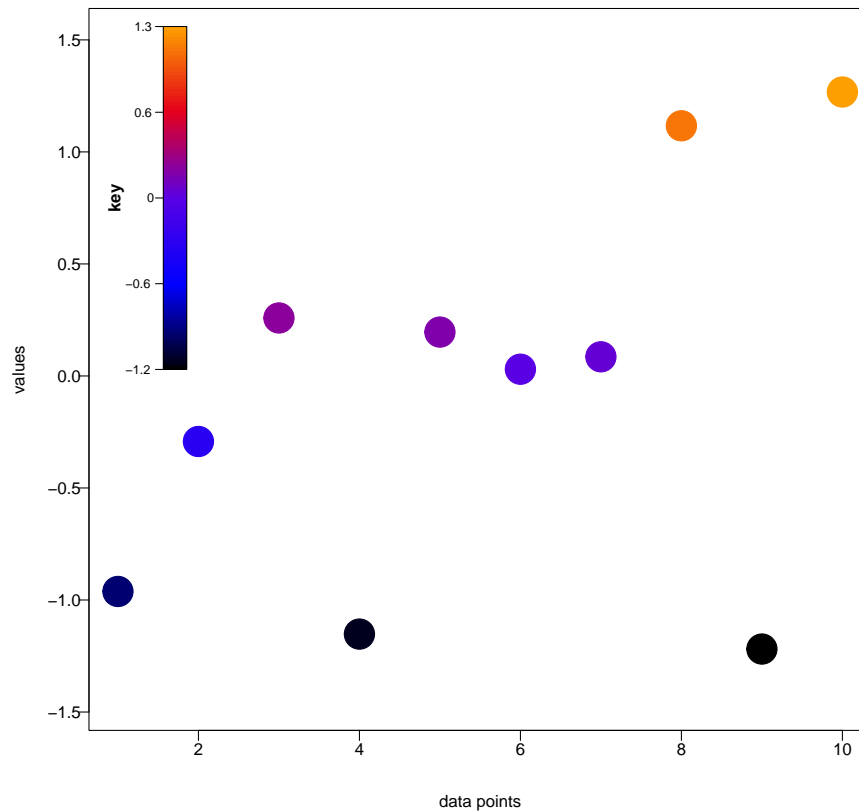

```
> text(-0.075,0.5,labels="overlap",font=2,adj=1)
> text(-0.075,-.5,labels="red",font=2,adj=1)
```

3.10.3 maptocolors

`maptocolors()` takes a vector of values and maps them to a color palette which can be used for plotting.

```
> set.seed(3)
> values = rnorm((1:10))
> colorpalette = SushiColors(5)
> plot(x=(1:10),y=values,col=maptocolors(values,colorpalette),
      pch=19,cex=4,xlab="data points",yaxt='n',ylim=range(values)*1.2)
> addlegend(range(values),title="key",palette=colorpalette,
      side='left',xoffset = -0.125,width=0.03,bottominset = 0.5, topinset = 0.025)
> axis(side=2,las=2)
```

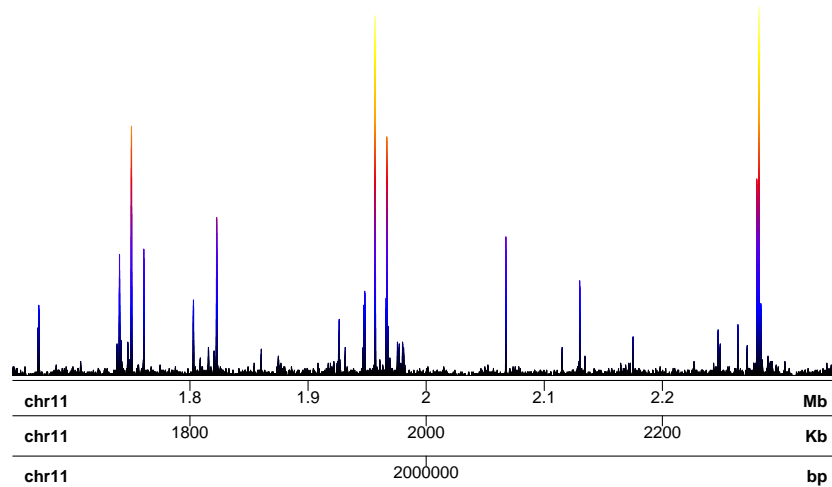

3.11 labeling functions

3.11.1 labelgenome

`labelgenome()` Add genome coordinates to the x-axis of a plot. The `line` argument can be used to offset the axis and `n` can be used to determine the desired number of tick marks.

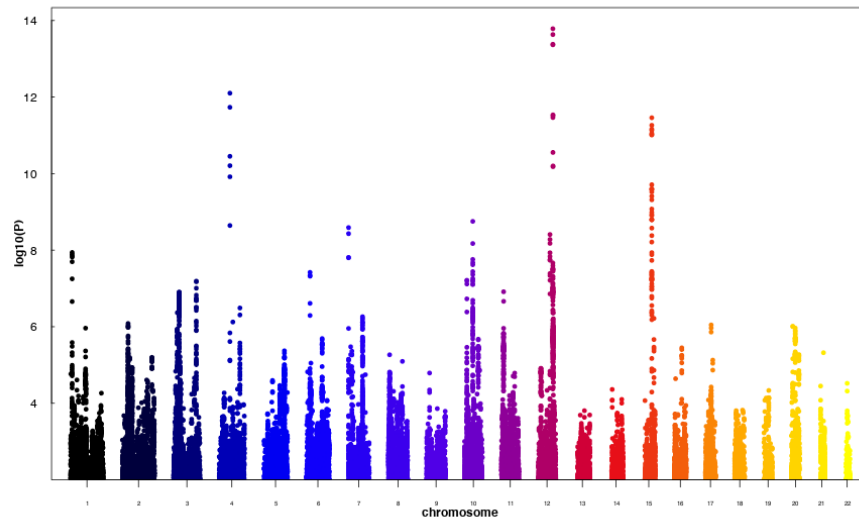

```
> par(mar=c(8,3,3,1),mgp=c(3, .3, 0))
> plotBedgraph(Sushi_DNaseI.bedgraph,chrom="chr11",chromstart=1650000,
               chromend=2350000,colorbycol=SushiColors(7))
> labelgenome(chrom="chr11",chromstart=1650000,chromend=2350000,
              side=1,n=4,scale="Mb",line=.25)
> labelgenome(chrom="chr11",chromstart=1650000,chromend=2350000,
              side=1,n=3,scale="Kb",line=2)
> labelgenome(chrom="chr11",chromstart=1650000,chromend=2350000,
              side=1,n=1,scale="bp",line=4)
```

Manhattan plots include multiple genomes and labeling the axes of Manhattan plots requires the same `genome` object and value of `space` that were used to in `plotManhattan()`

```
> plotManhattan(bedfile=Sushi_GWAS.bed,pvalues=Sushi_GWAS.bed[,5],
                 col=SushiColors(6),genome=Sushi_hg18_genome,
                 cex=0.75,space=0.05)
> labelgenome(genome=Sushi_hg18_genome,n=4,scale="Mb",
               edgeblankfraction=0.20,cex.axis=.5,space=0.05)
> axis(side=2,las=2,tcl=.2)
> mtext("log10(P)",side=2,line=1.75,cex=1,font=2)
> mtext("chromosome",side=1,line=1.75,cex=1,font=2)
```

pdf
2

3.11.2 labelplot

Plot labels and titles can be added with the `labelplot()` function.

```
> labelplot("A ", "Manhattan Plot")

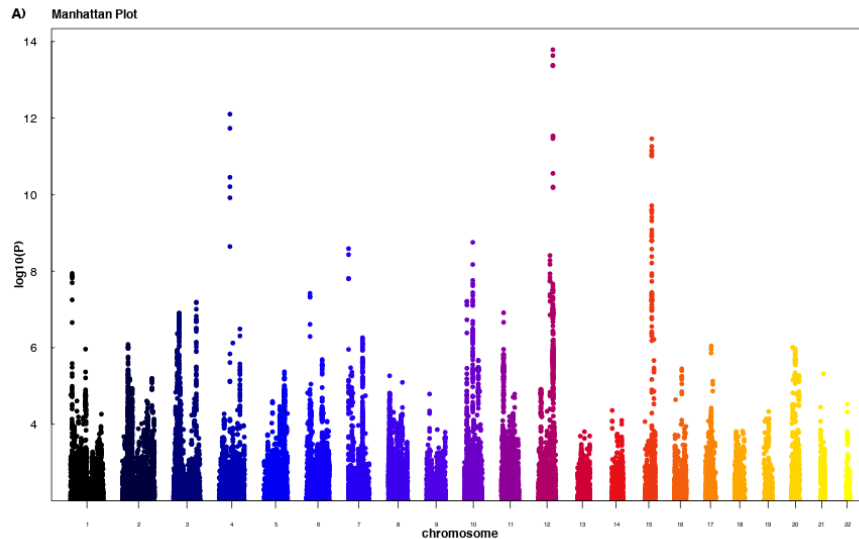

> plotManhattan(bedfile=Sushi_GWAS.bed, pvalues=Sushi_GWAS.bed[,5],
               col=SushiColors(6), genome=Sushi_hg18_genome,
               cex=0.75, space=0.05)

> labelgenome(genome=Sushi_hg18_genome, n=4, scale="Mb"
             , edgeblankfraction=0.20, cex.axis=.5, space=0.05)

> axis(side=2, las=2, tcl=.2)
> mtext("log10(P)", side=2, line=1.75, cex=1, font=2)
> mtext("chromosome", side=1, line=1.75, cex=1, font=2)
> labelplot("A ", "Manhattan Plot")
```

pdf

[1] TRUE

4 Tips

Other popular file formats such as BAM and GFF are not explicitly supported by Sushi. However, data stored in these formats can be easily converted to BED format using common command line tools such as the `bedtools` software suite available at <https://github.com/arq5x/bedtools2>. Some examples taken from the `bedtools` are shown below.

Convert BAM alignments to BED format.

```
bamToBed -i reads.bam > reads.bed
```

Convert BAM alignments to BED format using edit distance (NM) as the BED score.

```
bamToBed -i reads.bam -ed > reads.bed
```

Convert BAM alignments to BEDPE format.

```
bamToBed -i reads.bam -bedpe > reads.bedpe
```

These BED files can easily be read into R for use with Sushi using the following R command:

```
> read.table(file="reads.bed", sep="\t")
```

5 Appendix

For illustrative purposes we include a complex figure as published in the accompanying manuscript (Phanstiel, et al.).

```
1 library('Sushi')
2 pdfname = "vignettes/Figure_1.pdf"
3 Sushi_data = data(package = 'Sushi')
4 data(list = Sushi_data$results[,3])
5 makepdf = TRUE
