iCARE (Individualized Coherent Absolute Risk Estimation) Package

November 1, 2022

Load the iCARE library

```
> library(iCARE)
```

Load the breast cancer data and set the seed.

```
> data("bc_data", package="iCARE")
> set.seed(50)
```

Example 1: SNP-only model

In this example, we will estimate the risk of breast cancer in ages 50-80. A SNP-only model is fit, with no specific genotypes supplied for estimation. The population disease rates are from SEER.

```
> res_snps_miss = computeAbsoluteRisk(model.snp.info = bc_72_snps,
+                         model.disease.incidence.rates = bc_inc,
+                         model.competing.incidence.rates = mort_inc,
+                         apply.age.start = 50, apply.age.interval.length = 30,
+                         return.refs.risk = TRUE)

Note: You did not provide apply.snp.profile.  Will impute SNPs for 10000 people.
If require more, please provide apply.snp.profile input.
[1] "Note: As specified, the model does not adjust SNP imputations for family history."
   user  system elapsed
   9.74    0.25    9.98
```

Compute a summary of the risks.

```
> summary(res_snps_miss$refs.risk)

   Min. 1st Qu.  Median    Mean 3rd Qu.    Max.
0.05745 0.08666 0.09494 0.09600 0.10422 0.15882
```

Next, suppose we want to predict risk for three specific women whom we have genotyped; we can then call:

```
> res_snps_dat = computeAbsoluteRisk(model.snp.info = bc_72_snps,
+                       model.disease.incidence.rates = bc_inc,
+                       model.competing.incidence.rates = mort_inc,
+                       apply.age.start = 50, apply.age.interval.length = 30,
+                       apply.snp.profile = new_snp_prof,
+                       return.refs.risk = TRUE)

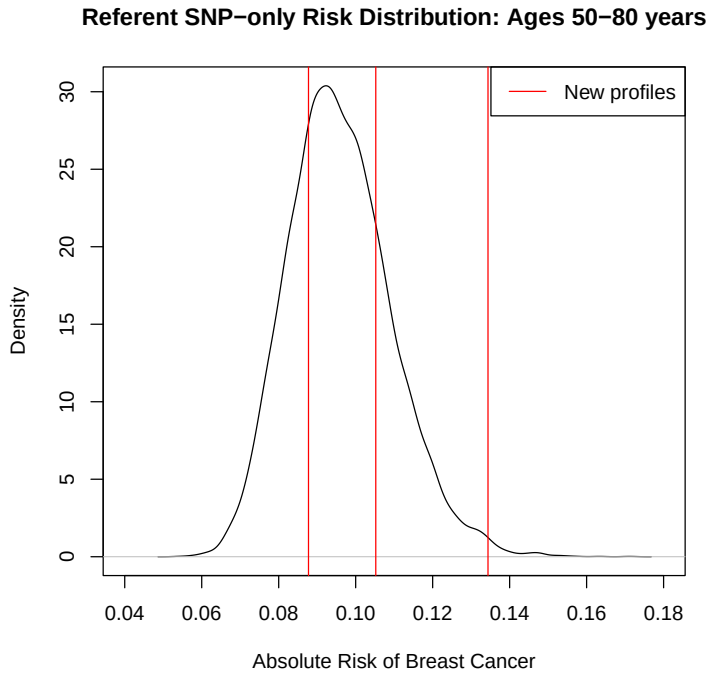
[1] "Note: As specified, the model does not adjust SNP imputations for family history."
   user  system elapsed
   0.53    0.11    0.64

> names(res_snps_dat)

[1] "risk"      "details"   "beta.used" "refs.risk"
```

These results allow us to create a useful plot showing the distribution of risks in our reference dataset and to add the risks of the three women to see where they fall on the population distribution.

```
> plot(density(res_snps_dat$refs.risk),
+            xlim = c(0.04,0.18), xlab = "Absolute Risk of Breast Cancer",
+            main = "Referent SNP-only Risk Distribution: Ages 50-80 years")
> abline(v = res_snps_dat$risk, col = "red")
> legend("topright", legend = "New profiles", col = "red", lwd = 1)
```



Example 2: Breast cancer risk model with risk-factors and SNPs

In this example, we will estimate the risk of breast cancer in ages 50-80 by fitting a model with classical risk factors and 72 SNPs, with three specific covariate profiles supplied for estimation (with some missing data). More details on risk factors are available in the manual.

```
> res_covs_snps = computeAbsoluteRisk(model.formula = bc_model_formula,
+                                     model.cov.info = bc_model_cov_info,
+                                     model.snp.info = bc_72_snps,
+                                     model.log.RR = bc_model_log_or,
+                                     model.ref.dataset = ref_cov_dat,
+                                     model.disease.incidence.rates = bc_inc,
+                                     model.competing.incidence.rates = mort_inc,
+                                     model.bin.fh.name = "famhist",
+                                     apply.age.start = 50,
+                                     apply.age.interval.length = 30,
+                                     apply.cov.profile = new_cov_prof,
+                                     apply.snp.profile = new_snp_prof,
+                                     return.refs.risk = TRUE)

   user  system elapsed
   1.75    0.22    1.97
```

In addition to summarizing and plotting the risk estimates, iCARE includes an option to view more detailed output, by calling:

```
> print(res_covs_snps$details)

```

Illustration of the validation component

We want to validate a model for predicting absolute risk of disease based on a combined model of classical risk factors and 72 SNPs using the nested case-control dataset.

The first step is to compute sampling weights. We fit a logistic regression model of inclusion depending on the case/control status, age of study entry and observed followup using the R function **glm**, as shown below:

```
> validation.cohort.data$inclusion = 0
> subjects_included = intersect(validation.cohort.data$id,
+                               validation.nested.case.control.data$id)
> validation.cohort.data$inclusion[subjects_included] = 1
> validation.cohort.data$observed.followup =
+                         validation.cohort.data$study.exit.age -
+                             validation.cohort.data$study.entry.age
> selection.model = glm(inclusion ~ observed.outcome
+                       * (study.entry.age + observed.followup),
```

```
+                                data = validation.cohort.data,
+                                family = binomial(link = "logit"))
> validation.nested.case.control.data$sampling.weights =
+         selection.model$fitted.values[validation.cohort.data$inclusion == 1]
```

The next step is to call the **ModelValidation** function to implement the validation analysis.

```
> data = validation.nested.case.control.data
> risk.model = list(model.formula = bc_model_formula,
+                   model.cov.info = bc_model_cov_info,
+                   model.snp.info = bc_72_snps,
+                   model.log.RR = bc_model_log_or,
+                   model.ref.dataset = ref_cov_dat,
+                   model.ref.dataset.weights = NULL,
+                   model.disease.incidence.rates = bc_inc,
+                   model.competing.incidence.rates = mort_inc,
+                   model.bin.fh.name = "famhist",
+                   apply.cov.profile = data[,all.vars(bc_model_formula)[-1]],
+                   apply.snp.profile = data[,bc_72_snps$snp.name],
+                   n.imp = 5, use.c.code = 1, return.lp = TRUE,
+                   return.refs.risk = TRUE)
> output = ModelValidation(study.data = data,
+                          total.followup.validation = TRUE,
+                          predicted.risk.interval = NULL,
+                          iCARE.model.object = risk.model,
+                          number.of.percentiles = 10)

   user  system elapsed
 153.02    0.04  160.51
```

We can also produce a set of useful plots showing the results of the validation analysis.

```
> plotModelValidation(study.data = data,validation.results = output)

NULL
```
