Calculation of the cost matrix

1 Problem statement and definitions

Let y_{nj} be the data value at position (genomic coordinate) $n = 1, \ldots, N$ for replicate array $j = 1, \ldots, J$. Hence we have J arrays and sequences of length N. The goal of this note is to describe an O(NJ) algorithm to calculate the cost matrix of a piecewise linear model for the segmentation of the $(1, \ldots, N)$ axis. It is implemented in the function *costMatrix* in the package *tilingArray*. The cost matrix is the input for a dynamic programming algorithm that finds the optimal (least squares) segmentation.

The cost matrix G_{km} is the sum of squared residuals for a segment from m to m + k - 1 (i.e. including m + k - 1 but excluding m + k),

$$G_{km} := \sum_{j=1}^{J} \sum_{n=m}^{m+k-1} (y_{nj} - \hat{\mu}_{km})^2$$
(1)

where $1 \le m \le m + k - 1 \le N$ and $\hat{\mu}_{km}$ is the mean of that segment,

$$\hat{\mu}_{km} = \frac{1}{Jk} \sum_{j=1}^{J} \sum_{n=m}^{m+k-1} y_{nj}.$$
(2)

Sidenote: a perhaps more straightforward definition of a cost matrix would be $\bar{G}_{m'm} = G_{(m'-m)m}$, the sum of squared residuals for a segment from m to m' - 1. I use version (1) because it makes it easier to use the condition of maximum segment length ($k \leq k_{max}$), which I need to get the algorithm from complexity $O(N^2)$ to O(N).

2 Algebra

$$G_{km} = \sum_{j=1}^{J} \sum_{n=m}^{m+k-1} (y_{nj} - \hat{\mu}_{km})^2$$
(3)

$$= \sum_{n,j} y_{nj}^2 - \frac{1}{Jk} \left(\sum_{n',j'} y_{n'j'} \right)^2$$
(4)

$$= \sum_{n} q_n - \frac{1}{Jk} \left(\sum_{n'} r_{n'} \right)^2 \tag{5}$$

with

$$q_n := \sum_j y_{nj}^2 \tag{6}$$

$$r_n := \sum_j y_{nj} \tag{7}$$

If **y** is an $N \times J$ matrix, then the N-vectors **q** and **r** can be obtained by

q = rowSums(y*y)
r = rowSums(y)

Now define

$$c_{\nu} = \sum_{n=1}^{\nu} r_n \tag{8}$$

$$d_{\nu} = \sum_{n=1}^{\nu} q_n \tag{9}$$

which be obtained from

$$c = cumsum(r)$$

 $d = cumsum(q)$

then (5) becomes

$$(d_{m+k-1} - d_{m-1}) - \frac{1}{Jk}(c_{m+k-1} - c_{m-1})^2$$
(10)
