

Package ‘mixOmics’

April 16, 2019

Type Package

Title Omics Data Integration Project

Version 6.6.2

Depends R (>= 3.5.0), MASS, lattice, ggplot2

Imports igraph, ellipse, corpcor, RColorBrewer, parallel, dplyr,
tidyr, reshape2, methods, matrixStats, rARPACK, gridExtra,
grDevices, graphics, stats, utils

Suggests BiocStyle, knitr, rmarkdown, testthat, rgl

Author Kim-Anh Le Cao, Florian Rohart, Ignacio Gonzalez, Sebastien Dejean with key contributors Benoit Gautier, Francois Bartolo and contributions from Pierre Monget, Jeff Coquery, FangZou Yao, Benoit Liquet.

Maintainer Kim-Anh Le Cao <kimanh.lecao@unimelb.edu.au>

Description Multivariate methods are well suited to large omics data sets where the number of variables (e.g. genes, proteins, metabolites) is much larger than the number of samples (patients, cells, mice). They have the appealing properties of reducing the dimension of the data by using instrumental variables (components), which are defined as combinations of all variables. Those components are then used to produce useful graphical outputs that enable better understanding of the relationships and correlation structures between the different data sets that are integrated. mixOmics offers a wide range of multivariate methods for the exploration and integration of biological datasets with a particular focus on variable selection. The package proposes several sparse multivariate models we have developed to identify the key variables that are highly correlated, and/or explain the biological outcome of interest. The data that can be analysed with mixOmics may come from high throughput sequencing technologies, such as omics data (transcriptomics, metabolomics, proteomics, metagenomics etc) but also beyond the realm of omics (e.g. spectral imaging). The methods implemented in mixOmics can also handle missing values without having to delete entire rows with missing data. A non exhaustive list of methods include variants of generalised Canonical Correlation Analysis, sparse Partial Least Squares and sparse Discriminant Analysis. Recently we implemented integrative methods to combine multiple data sets: N-integration with variants of Generalised Canonical Correlation Analysis and P-integration with variants of multi-group Partial Least Squares.

auroc *Area Under the Curve (AUC) and Receiver Operating Characteristic (ROC) curves for supervised classification*

Description

Calculates the AUC and plots ROC for supervised objects from `s/plsda`, `mint.s/plsda` and `block.plsda`, `block.splsda` or `wrapper.sgccda`.

Usage

```
## S3 method for class 'mixo_plsda'
auroc(object, newdata = object$input.X, outcome.test = as.factor(object$Y),
multilevel = NULL, plot = TRUE, roc.comp = 1, ...)
```

```
## S3 method for class 'mixo_splsda'
auroc(object, newdata = object$input.X, outcome.test = as.factor(object$Y),
multilevel = NULL, plot = TRUE, roc.comp = 1, ...)
```

```
## S3 method for class 'mint.plsda'
auroc(object, newdata = object$X, outcome.test = as.factor(object$Y),
study.test = object$study, multilevel = NULL, plot = TRUE, roc.comp = 1,
roc.study = "global", ...)
```

```
## S3 method for class 'mint.splsda'
auroc(object, newdata = object$X, outcome.test = as.factor(object$Y),
study.test = object$study, multilevel = NULL, plot = TRUE, roc.comp = 1,
roc.study = "global", ...)
```

```
## S3 method for class 'sgccda'
auroc(object, newdata = object$X, outcome.test = as.factor(object$Y),
multilevel = NULL, plot = TRUE, roc.block = 1, roc.comp = 1, ...)
```

Arguments

<code>object</code>	Object of class inherited from one of the following supervised analysis function: "plsda", "splsda", "mint.plsda", "mint.splsda", "block.splsda" or "wrapper.sgccda"
<code>newdata</code>	numeric matrix of predictors, by default set to the training data set (see details).
<code>outcome.test</code>	Either a factor or a class vector for the discrete outcome, by default set to the outcome vector from the training set (see details).
<code>study.test</code>	For MINT objects, grouping factor indicating which samples of newdata are from the same study. Overlap with <code>object\$study</code> are allowed.
<code>multilevel</code>	Sample information when a newdata matrix is input and when multilevel decomposition for repeated measurements is required. A numeric matrix or data frame indicating the repeated measures on each individual, i.e. the individuals ID. See examples in <code>splsda</code> .
<code>plot</code>	Whether the ROC curves should be plotted, by default set to TRUE (see details).

<code>roc.comp</code>	Specify the component (integer) for which the ROC will be plotted from the multivariate model, default to 1.
<code>roc.block</code>	Specify the block number (integer) or the name of the block (set of characters) for which the ROC will be plotted for a <code>block.plsda</code> or <code>block.splsda</code> object, default to 1.
<code>roc.study</code>	Specify the study for which the ROC will be plotted for a <code>mint.plsda</code> or <code>mint.splsda</code> object, default to "global".
<code>...</code>	external optional arguments for plotting

Details

For more than two classes in the categorical outcome Y, the AUC is calculated as one class vs. the other and the ROC curves one class vs. the others are output.

The ROC and AUC are calculated based on the predicted scores obtained from the `predict` function applied to the multivariate methods (`predict(object)$predict`). Our multivariate supervised methods already use a prediction threshold based on distances (see `predict`) that optimally determine class membership of the samples tested. As such AUC and ROC are not needed to estimate the performance of the model (see `perf`, `tune` that report classification error rates). We provide those outputs as complementary performance measures.

The pvalue is from a Wilcoxon test between the predicted scores between one class vs the others.

External independent data set (`newdata`) and outcome (`outcome.test`) can be input to calculate AUROC. The external data set must have the same variables as the training data set (`object$X`).

If `newdata` is not provided, AUROC is calculated from the training data set, and may result in overfitting (too optimistic results).

Note that for `mint.plsda` and `mint.splsda` objects, if `roc.study` is different from "global", then `newdata`, `outcome.test` and `sstudy.test` are not used.

Value

Depending on the type of object used, a list that contains: The AUC and Wilcoxon test pvalue for each 'one vs other' classes comparison performed, either per component (`splsda`, `plsda`, `mint.plsda`, `mint.splsda`), or per block and per component (`wrapper.sgccda`, `block.plsda`, `block.splsda`).

Examples

```
## example with PLSDA, 2 classes
# -----
data(breast.tumors)
X <- breast.tumors$gene.exp
Y <- breast.tumors$sample$treatment

plsda.breast <- plsda(X, Y, ncomp = 2)
auc.plsda.breast = auroc(plsda.breast, ncomp = 1)
```

```

## Not run:
## example with sPLSDA
# -----
splstda.breast <- splstda(X, Y, ncomp = 2, keepX = c(25, 25))
auROC(plstda.breast, plot = FALSE)

## example with sPLSDA with 4 classes
# -----
data(liver.toxicity)
X <- as.matrix(liver.toxicity$gene)
# Y will be transformed as a factor in the function,
# but we set it as a factor to set up the colors.
Y <- as.factor(liver.toxicity$treatment[, 4])

splstda.liver <- splstda(X, Y, ncomp = 2, keepX = c(20, 20))
auc.splstda.liver = auROC(splstda.liver, ncomp = 1)

## example with mint.plstda
# -----
data(stemcells)

res = mint.plstda(X = stemcells$gene, Y = stemcells$celltype, ncomp = 3,
study = stemcells$study)
auc.mint.plstda = auROC(res, plot = FALSE)

## example with mint.splstda
# -----
res = mint.splstda(X = stemcells$gene, Y = stemcells$celltype, ncomp = 3, keepX = c(10, 5, 15),
study = stemcells$study)
auc.mint.splstda = auROC(res, plot = TRUE, roc.comp = 3)

## example with block.plstda
# -----
data(nutrimouse)
data = list(gene = nutrimouse$gene, lipid = nutrimouse$lipid)
# with this design, all blocks are connected
design = matrix(c(0,1,1,0), ncol = 2, nrow = 2,
byrow = TRUE, dimnames = list(names(data), names(data)))

block.plstda.nutri = block.plstda(X = data, Y = nutrimouse$diet)
auc.block.plstda.nutri = auROC(block.plstda.nutri, block = 'lipid')

## example with block.splstda
# -----
list.keepX = list(gene = rep(10, 2), lipid = rep(5,2))
block.splstda.nutri = block.splstda(X = data, Y = nutrimouse$diet, keepX = list.keepX)
auc.block.splstda.nutri = auROC(block.splstda.nutri, block = 1)

## End(Not run)

```

Description

Calculate prediction areas that can be used in `plotIndiv` to shade the background.

Usage

```
background.predict(object, comp.predicted = 1, dist = "max.dist",  
xlim = NULL, ylim = NULL, resolution = 100)
```

Arguments

<code>object</code>	A list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.
<code>comp.predicted</code>	Matrix response for a multivariate regression framework. Data should be continuous variables (see <code>block.splsda</code> for supervised classification and factor response)
<code>dist</code>	distance to use to predict the class of new data, should be a subset of " <code>centroids.dist</code> ", " <code>mahalanobis.dist</code> " or " <code>max.dist</code> " (see <code>predict</code>).
<code>xlim,ylim</code>	numeric list of vectors of length 2, giving the x and y coordinates ranges for the simulated data. By default will be 1.2* the range of <code>object\$variables\$X[,i]</code>
<code>resolution</code>	A total of <code>resolution*resolution</code> data are simulated between <code>xlim[1]</code> , <code>xlim[2]</code> , <code>ylim[1]</code> and <code>ylim[2]</code> .

Details

`background.predict` simulates `resolution*resolution` points within the rectangle defined by `xlim` on the x-axis and `ylim` on the y-axis, and then predicts the class of each point (defined by two coordinates). The algorithm estimates the predicted area for each class, defined as the 2D surface where all points are predicted to be of the same class. A polygon is returned and should be passed to `plotIndiv` for plotting the actual background.

Note that by default `xlim` and `ylim` will create a rectangle of simulated data that will cover the plotted area of `plotIndiv`. However, if you use `plotIndiv` with `ellipse=TRUE` or if you set `xlim` and `ylim`, then you will need to adapt `xlim` and `ylim` in `background.predict`.

Also note that the white frontier that defines the predicted areas when plotting with `plotIndiv` can be reduced by increasing `resolution`.

More details about the prediction distances in `?predict` and the supplemental material of the `mixOmics` article (Rohart et al. 2017).

Value

`background.predict` returns a list of coordinates to be used with `polygon` to draw the predicted area for each class.

# -----
data(liver.toxicity)
X = liver.toxicity$gene
Y = as.factor(liver.toxicity$treatment[, 4])

plsda.liver <- plsda(X, Y, ncomp = 2)

# calculating background for the two first components, and the mahalanobis distance
background = background.predict(plsda.liver, comp.predicted = 2, dist = "mahalanobis.dist")

plotIndiv(plsda.liver, background = background, legend = TRUE)

## End(Not run)
```

block.pls

N-integration with Projection to Latent Structures models (PLS)

Description

Integration of multiple data sets measured on the same samples or observations, ie. N-integration. The method is partly based on Generalised Canonical Correlation Analysis.

Usage

```
block.pls(X,
Y,
```

```

indY,
ncomp = 2,
design,
scheme,
mode,
scale = TRUE,
init ,
tol = 1e-06,
max.iter = 100,
near.zero.var = FALSE,
all.outputs = TRUE)

```

Arguments

X	A list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.
Y	Matrix response for a multivariate regression framework. Data should be continuous variables (see block.splsda for supervised classification and factor response)
indY	To supply if Y is missing, indicates the position of the matrix response in the list X
ncomp	the number of components to include in the model. Default to 2. Applies to all blocks.
design	numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strenght of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
scheme	Either "horst", "factorial" or "centroid". Default = horst, see reference.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details. Default = regression.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances. Default = TRUE.
init	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default = svd.single.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default = FALSE.
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

block.spls function fits a horizontal integration PLS model with a specified number of components per block). An outcome needs to be provided, either by Y or by its position indY in the list of blocks X. Multi (continuous)response are supported. X and Y can contain missing values. Missing

values are handled by being disregarded during the cross product computations in the algorithm `block.pls` without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the `nipals` function.

The type of algorithm to use is specified with the `mode` argument. Four PLS algorithms are available: PLS regression ("`regression`"), PLS canonical analysis ("`canonical`"), redundancy analysis ("`invariant`") and the classical PLS algorithm ("`classic`") (see References and `?pls` for more details).

Note that our method is partly based on Generalised Canonical Correlation Analysis and differs from the MB-PLS approaches proposed by Kowalski et al., 1989, *J Chemom* 3(1) and Westerhuis et al., 1998, *J Chemom*, 12(5).

Value

`block.pls` returns an object of class "`block.pls`", a list that contains the following components:

<code>X</code>	the centered and standardized original predictor matrix.
<code>indY</code>	the position of the outcome <code>Y</code> in the output list <code>X</code> .
<code>ncomp</code>	the number of components included in the model for each block.
<code>mode</code>	the algorithm used to fit the model.
<code>variates</code>	list containing the variates of each block of <code>X</code> .
<code>loadings</code>	list containing the estimated loadings for the variates.
<code>names</code>	list containing the names to be used for individuals and variables.
<code>nzv</code>	list containing the zero- or near-zero predictors information.
<code>iter</code>	Number of iterations of the algorithm for each component
<code>explained_variance</code>	Percentage of explained variance for each component and each block

```

block.plsda

*N-integration with Projection to Latent Structures models (PLS) with
Discriminant Analysis*

Description

Integration of multiple data sets measured on the same samples or observations to classify a discrete outcome, ie. N-integration with Discriminant Analysis. The method is partly based on Generalised Canonical Correlation Analysis.

Usage

```

block.plsda(X,
Y,
indY,
ncomp = 2,
design,
scheme,
mode,
scale = TRUE,
init = "svd",
tol = 1e-06,
max.iter = 100,
near.zero.var = FALSE,
all.outputs = TRUE)

```

Arguments

X	A list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.
Y	A factor or a class vector indicating the discrete outcome of each sample.
indY	To be supplied if Y is missing, indicates the position of the factor / class vector outcome in the list X
ncomp	the number of components to include in the model. Default to 2. Applies to all blocks.
design	numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strenght of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
scheme	Either "horst", "factorial" or "centroid". Default = horst, see reference.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details. Default = regression.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances. Default = TRUE.
init	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default = svd.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default = FALSE.
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

block.plsda function fits a horizontal integration PLS-DA model with a specified number of components per block). A factor indicating the discrete outcome needs to be provided, either by Y or by its position indY in the list of blocks X.

X can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm block.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and ?pls for more details).

Note that our method is partly based on Generalised Canonical Correlation Analysis and differs from the MB-PLS approaches proposed by Kowalski et al., 1989, J Chemom 3(1) and Westerhuis et al., 1998, J Chemom, 12(5).

Value

block.plsda returns an object of class "block.plsda", "block.pls", a list that contains the following components:

X	the centered and standardized original predictor matrix.
indY	the position of the outcome Y in the output list X.
ncomp	the number of components included in the model for each block.
mode	the algorithm used to fit the model.
variates	list containing the variates of each block of X.
loadings	list containing the estimated loadings for the variates.
names	list containing the names to be used for individuals and variables.
nzv	list containing the zero- or near-zero predictors information.
iter	Number of iterations of the algorithm for each component
explained_variance	Percentage of explained variance for each component and each block

block.spls

N-integration and feature selection with sparse Projection to Latent Structures models (sPLS)

Description

Integration of multiple data sets measured on the same samples or observations, with variable selection in each data set, ie. N-integration. The method is partly based on Generalised Canonical Correlation Analysis.

Usage

```

block.spls(X,
Y,
indY,
ncomp = 2,
keepX,
keepY,
design,
scheme,
mode,
scale = TRUE,
init ,
tol = 1e-06,
max.iter = 100,
near.zero.var = FALSE,
all.outputs = TRUE)

```

Arguments

<code>X</code>	A list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.
<code>Y</code>	Matrix response for a multivariate regression framework. Data should be continuous variables (see <code>block.splsda</code> for supervised classification and factor response)
<code>indY</code>	To supply if Y is missing, indicates the position of the matrix response in the list X
<code>ncomp</code>	the number of components to include in the model. Default to 2. Applies to all blocks.
<code>keepX</code>	A list of same length as X. Each entry is the number of variables to select in each of the blocks of X for each component. By default all variables are kept in the model.
<code>keepY</code>	Only if Y is provided. Each entry is the number of variables to select in each of the blocks of Y for each component.
<code>design</code>	numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strength of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. If Y is provided instead of <code>indY</code> , the design matrix is changed to include relationships to Y.
<code>scheme</code>	Either "horst", "factorial" or "centroid". Default = horst, see reference.
<code>mode</code>	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details. Default = regression.
<code>scale</code>	boolean. If <code>scale = TRUE</code> , each block is standardized to zero means and unit variances. Default = TRUE.
<code>init</code>	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default = svd.single.
<code>tol</code>	Convergence stopping value.
<code>max.iter</code>	integer, the maximum number of iterations.
<code>near.zero.var</code>	boolean, see the internal <code>nearZeroVar</code> function (should be set to TRUE in particular for data with many zero values). Default = FALSE.
<code>all.outputs</code>	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

`block.spls` function fits a horizontal sPLS model with a specified number of components per block). An outcome needs to be provided, either by Y or by its position `indY` in the list of blocks X. Multi (continuous)response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm `block.pls` without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the `nipals` function.

The type of algorithm to use is specified with the `mode` argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and `?pls` for more details).

Note that our method is partly based on sparse Generalised Canonical Correlation Analysis and differs from the MB-PLS approaches proposed by Kowalski et al., 1989, *J Chemom* 3(1), Westerhuis et al., 1998, *J Chemom*, 12(5) and sparse variants Li et al., 2012, *Bioinformatics* 28(19); Karaman et al (2014), *Metabolomics*, 11(2); Kawaguchi et al., 2017, *Biostatistics*.

Variable selection is performed on each component for each block of X, and for Y if specified, via input parameter `keepX` and `keepY`.

Note that if Y is missing and `indY` is provided, then variable selection on Y is performed by specifying the input parameter directly in `keepX` (no `keepY` is needed).

Value

`block.spls` returns an object of class "block.spls", a list that contains the following components:

<code>X</code>	the centered and standardized original predictor matrix.
<code>indY</code>	the position of the outcome Y in the output list X.
<code>ncomp</code>	the number of components included in the model for each block.
<code>mode</code>	the algorithm used to fit the model.
<code>keepX</code>	Number of variables used to build each component of each block
<code>keepY</code>	Number of variables used to build each component of Y
<code>variates</code>	list containing the variates of each block of X.
<code>loadings</code>	list containing the estimated loadings for the variates.
<code>names</code>	list containing the names to be used for individuals and variables.
<code>nzv</code>	list containing the zero- or near-zero predictors information.
<code>iter</code>	Number of iterations of the algorithm for each component
<code>explained_variance</code>	Percentage of explained variance for each component and each block

block.splsda

N-integration and feature selection with Projection to Latent Structures models (PLS) with sparse Discriminant Analysis

Description

Integration of multiple data sets measured on the same samples or observations to classify a discrete outcome to classify a discrete outcome and select features from each data set, ie. N-integration with sparse Discriminant Analysis. The method is partly based on Generalised Canonical Correlation Analysis.

Usage

```
block.splsda(X,
Y,
indY,
ncomp = 2,
keepX,
design,
scheme,
mode,
scale = TRUE,
init = "svd",
tol = 1e-06,
```

```
max.iter = 100,
near.zero.var = FALSE,
all.outputs = TRUE)
```

Arguments

X	A list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in matrices, samples x variables, with samples order matching in all data sets.
Y	A factor or a class vector indicating the discrete outcome of each sample.
indY	To be supplied if Y is missing, indicates the position of the factor / class vector outcome in the list X
ncomp	the number of components to include in the model. Default to 2. Applies to all blocks.
keepX	A list of same length as X. Each entry is the number of variables to select in each of the blocks of X for each component. By default all variables are kept in the model.
design	numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strenght of the relationship to be modelled between two blocks; a value of 0 indicates no relationship, 1 is the maximum value. If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
scheme	Either "horst", "factorial" or "centroid". Default = horst, see reference.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details. Default = regression.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances. Default = TRUE.
init	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default = svd.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default = FALSE.
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

block.splsda function fits a horizontal integration PLS-DA model with a specified number of components per block). A factor indicating the discrete outcome needs to be provided, either by Y or by its position indY in the list of blocks X.

X can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm block.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis

("invariant") and the classical PLS algorithm ("classic") (see References and ?pls for more details).

Note that our method is partly based on sparse Generalised Canonical Correlation Analysis and differs from the MB-PLS approaches proposed by Kowalski et al., 1989, *J Chemom* 3(1), Westerhuis et al., 1998, *J Chemom*, 12(5) and sparse variants Li et al., 2012, *Bioinformatics* 28(19); Karaman et al (2014), *Metabolomics*, 11(2); Kawaguchi et al., 2017, *Biostatistics*.

Variable selection is performed on each component for each block of X if specified, via input parameter keepX.

Value

block.splsda returns an object of class "block.splsda", "block.spls", a list that contains the following components:

X	the centered and standardized original predictor matrix.
indY	the position of the outcome Y in the output list X.
ncomp	the number of components included in the model for each block.
mode	the algorithm used to fit the model.
keepX	Number of variables used to build each component of each block
variates	list containing the variates of each block of X.
loadings	list containing the estimated loadings for the variates.
names	list containing the names to be used for individuals and variables.
nzv	list containing the zero- or near-zero predictors information.
iter	Number of iterations of the algorithm for each component
weights	Correlation between the variate of each block and the variate of the outcome. Used to weight predictions.
explained_variance	Percentage of explained variance for each component and each block

breast.TCGA

Breast Cancer multi omics data from TCGA

Description

This data set is a small subset of the full data set from The Cancer Genome Atlas that can be analysed with the DIABLO framework. It contains the expression or abundance of three matching omics data sets: mRNA, miRNA and proteomics for 150 breast cancer samples (Basal, Her2, Luminal A) in the training set, and 70 samples in the test set. The test set is missing the proteomics data set.

Usage

```
data(breast.TCGA)
```

Format

A list containing two data sets, `data.train` and `data.test` which both include:

miRNA data frame with 150 (70) rows and 184 columns in the training (test) data set. The expression levels of 184 miRNA.

mRNA data frame with 150 (70) rows and 520 columns in the training (test) data set. The expression levels of 200 mRNA.

protein data frame with 150 (70) rows and 142 columns in the training data set only. The abundance of 142 proteins.

subtype a factor indicating the breast cancer subtypes in the training (length of 150) and test (length of 70) sets.

Details

The data come from The Cancer Genome Atlas (TCGA, <http://cancergenome.nih.gov/>). We divided the data into a training (discovery) and test (validation) set. The protein dataset which had a limited number of subjects available was used to allocate subjects into the training set only, while the test set included all remaining subject. Each data set was normalised and pre-processed. For illustrative purposes we drastically filtered the data here.

Value

none

Source

The raw data were downloaded from <http://cancergenome.nih.gov/>. The normalised and filtered data we analysed with DIABLO are available on www.mixOmics.org/mixDIABLO

breast.tumors

Human Breast Tumors Data

Description

This data set contains the expression of 1,000 genes in 47 surgical specimens of human breast tumours from 17 different individuals before and after chemotherapy treatment.

Usage

`data(breast.tumors)`

Format

A list containing the following components:

`gene.exp` data matrix with 47 rows and 1000 columns. Each row represents an experimental sample, and each column a single gene.

`sample` a list containing two character vector components: `name` the name of the samples, and `treatment` the treatment status.

`genes` a list containing two character vector components: `name` the name of the genes, and `description` the description of each gene.

Details

This data consists of 47 breast cancer samples and 1753 cDNA clones pre-selected by Perez-Enciso *et al.* (2003) to draw their Fig. 1. The authors selected 47 samples for which there was information at least before or before and after chemotherapy treatment. There were 20 tumours that were microarrayed both before and after treatment. For illustrative purposes we then randomly selected 1000 cDNA clones for this data set.

Value

none

Source

The Human Breast Tumors dataset is a companion resource for the paper of Perou *et al.* (2000), and was downloaded from the Stanford Genomics Breast Cancer Consortium Portal http://genome-www.stanford.edu/breast_cancer/molecularportraits/download.shtml

cim

Clustered Image Maps (CIMs) ("heat maps")

Description

This function generates color-coded Clustered Image Maps (CIMs) ("heat maps") to represent "high-dimensional" data sets.

Usage

```
cim(mat,
     color = NULL,
     row.names = TRUE,
     col.names = TRUE,
     row.sideColors = NULL,
     col.sideColors = NULL,
     row.cex = NULL,
     col.cex = NULL,
     threshold = 0,
     cluster = "both",
     dist.method = c("euclidean", "euclidean"),
     clust.method = c("complete", "complete"),
     cut.tree = c(0, 0),
     transpose = FALSE,
     symkey = TRUE,
```

```

keysize = c(1, 1),
keysize.label = 1,
zoom = FALSE,
title = NULL,
xlab = NULL,
ylab = NULL,
margins = c(5, 5),
lhei = NULL,
lwid = NULL,
comp=NULL,
center = TRUE,
scale = FALSE,
mapping = "XY",
legend= NULL,
save = NULL,
name.save = NULL)

```

Arguments

<code>mat</code>	numeric matrix of values to be plotted. Alternatively, an object of class inheriting from "pca", "spca", "ipca", "sipca", "rcc", "pls", "spl", "plsda", "splda", "mlspl" or "mlsplda" (where "ml" stands for multilevel).
<code>color</code>	a character vector of colors such as that generated by terrain.colors , topo.colors , rainbow , color.jet or similar functions.
<code>row.names, col.names</code>	logical, should the name of rows and/or columns of <code>mat</code> be shown? If TRUE (defaults) <code>rownames(mat)</code> and/or <code>colnames(mat)</code> are used. Possible character vectors with row and/or column labels can be used.
<code>row.sideColors</code>	(optional) character vector of length <code>nrow(mat)</code> containing the color names for a vertical side bar that may be used to annotate the rows of <code>mat</code> .
<code>col.sideColors</code>	(optional) character vector of length <code>ncol(mat)</code> containing the color names for a horizontal side bar that may be used to annotate the columns of <code>mat</code> .
<code>row.cex, col.cex</code>	positive numbers, used as <code>cex.axis</code> in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.
<code>mapping</code>	character string indicating whether to map "X", "Y" or "XY"-association matrix. See Details.
<code>cluster</code>	character string indicating whether to cluster "none", "row", "column" or "both". Defaults to "both".
<code>dist.method</code>	character vector of length two. The distance measure used in clustering rows and columns. Possible values are "correlation" for Pearson correlation and all the distances supported by dist , such as "euclidean", etc.
<code>clust.method</code>	character vector of length two. The agglomeration method to be used for rows and columns. Accepts the same values as in hclust such as "ward", "complete", etc.
<code>cut.tree</code>	numeric vector of length two with components in [0,1]. The height proportions where the trees should be cut for rows and columns, if these are clustered.
<code>comp</code>	atomic or vector of positive integers. The components to adequately account for the data association. For a non sparse method, the similarity matrix is

	computed based on the variates and loading vectors of those specified components. For a sparse approach, the similarity matrix is computed based on the variables selected on those specified components. See example. Defaults to <code>comp = 1:object\$ncomp</code> .
<code>transpose</code>	logical indicating if the matrix should be transposed for plotting. Defaults to <code>FALSE</code> .
<code>center</code>	either a logical value or a numeric vector of length equal to the number of columns of <code>mat</code> . See <code>scale</code> function.
<code>scale</code>	either a logical value or a numeric vector of length equal to the number of columns of <code>mat</code> . See <code>scale</code> function.
<code>threshold</code>	numeric between 0 and 1. Variables with correlations below this threshold in absolute value are not plotted. To use only when mapping is "XY".
<code>symkey</code>	boolean indicating whether the color key should be made symmetric about 0. Defaults to <code>TRUE</code> .
<code>keysize</code>	vector of length two, indicating the size of the color key.
<code>keysize.label</code>	vector of length 1, indicating the size of the labels and title of the color key.
<code>zoom</code>	logical. Whether to use zoom for interactive zoom. See Details.
<code>title, xlab, ylab</code>	title, <i>x</i> - and <i>y</i> -axis titles; default to none.
<code>margins</code>	numeric vector of length two containing the margins (see <code>par(mar)</code>) for column and row names respectively.
<code>lhei, lwid</code>	arguments passed to <code>layout</code> to divide the device up into two (or three if a side color is drawn) rows and two columns, with the row-heights <code>lhei</code> and the column-widths <code>lwid</code> .
<code>legend</code>	A list indicating the legend for each group, the color vector, title of the legend and <code>cex</code> .
<code>save</code>	should the plot be saved? If so, argument to be set to either <code>'jpeg'</code> , <code>'tiff'</code> , <code>'png'</code> or <code>'pdf'</code> .
<code>name.save</code>	character string for the name of the file to be saved.

Details

One matrix Clustered Image Map (default method) is a 2-dimensional visualization of a real-valued matrix (basically `image(t(mat))`) with rows and/or columns reordered according to some hierarchical clustering method to identify interesting patterns. Generated dendrograms from clustering are added to the left side and to the top of the image. By default the used clustering method for rows and columns is the *complete linkage* method and the used distance measure is the distance *euclidean*.

In `"pca"`, `"spca"`, `"ipca"`, `"sipca"`, `"plsda"`, `"spllda"` and multilevel variants methods the `mat` matrix is `object$X`.

For the remaining methods, if `mapping = "X"` or `mapping = "Y"` the `mat` matrix is `object$X` or `object$Y` respectively. If `mapping = "XY"`:

- in `rcc` method, the matrix `mat` is created where element (j, k) is the scalar product value between every pairs of vectors in dimension `length(comp)` representing the variables X_j and Y_k on the axis defined by Z_i with i in `comp`, where Z_i is the equiangular vector between the i -th X and Y canonical variate.

- in pls, spls and multilevel spls methods, if `object$mode` is "regression", the element (j, k) of the matrix `mat` is given by the scalar product value between every pairs of vectors in dimension `length(comp)` representing the variables X_j and Y_k on the axis defined by U_i with i in `comp`, where U_i is the i -th X variate. If `object$mode` is "canonical" then X_j and Y_k are represented on the axis defined by U_i and V_i respectively.

By default four components will be displayed in the plot. At the top left is the color key, top right is the column dendrogram, bottom left is the row dendrogram, bottom right is the image plot. When `sideColors` are provided, an additional row or column is inserted in the appropriate location. This layout can be overridden by specifying appropriate values for `lwid` and `lhei`. `lwid` controls the column width, and `lhei` controls the row height. See the help page for [layout](#) for details on how to use these arguments.

For visualization of "high-dimensional" data sets, a nice zooming tool was created. `zoom = TRUE` open a new device, one for CIM, one for zoom-out region and define an interactive 'zoom' process: click two points at imagen map region by pressing the first mouse button. It then draws a rectangle around the selected region and zoom-out this at new device. The process can be repeated to zoom-out other regions of interest.

The zoom process is terminated by clicking the second button and selecting 'Stop' from the menu, or from the 'Stop' menu on the graphics window.

Value

A list containing the following components:

<code>M</code>	the mapped matrix used by <code>cim</code> .
<code>rowInd</code> , <code>colInd</code>	row and column index permutation vectors as returned by <code>order.dendrogram</code> .
<code>ddr</code> , <code>ddc</code>	object of class "dendrogram" which describes the row and column trees produced by <code>cim</code> .
<code>mat.cor</code>	the correlation matrix used for the heatmap. Available only when <code>mapping = "XY"</code> .
<code>row.names</code> , <code>col.names</code>	character vectors with row and column labels used.
<code>row.sideColors</code> , <code>col.sideColors</code>	character vector containing the color names for vertical and horizontal side bars used to annotate the rows and columns.

```

cimDiablo

Clustered Image Maps (CIMs) ("heat maps") for DIABLO

Description

This function generates color-coded Clustered Image Maps (CIMs) ("heat maps") to represent "high-dimensional" data sets analysed with DIABLO.

Usage

```

cimDiablo(object,
color = NULL,
color.Y,
color.blocks,
comp = NULL,
margins = c(2, 15),
legend.position = "topright",
transpose = FALSE,
row.names = TRUE,

```

```
col.names = TRUE,
size.legend = 1.5)
```

Arguments

object	An object of class inheriting from "block.splsda".
color	a character vector of colors such as that generated by <code>terrain.colors</code> , <code>topo.colors</code> , <code>rainbow</code> , <code>color.jet</code> or similar functions.
color.Y	a character vector of colors to be used for the levels of the outcome
color.blocks	a character vector of colors to be used for the blocks
comp	positive integer. The similarity matrix is computed based on the variables selected on those specified components. See example. Defaults to <code>comp = 1</code> .
margins	numeric vector of length two containing the margins (see <code>par(mar)</code>) for column and row names respectively.
legend.position	position of the legend, one of "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center".
transpose	logical indicating if the matrix should be transposed for plotting. Defaults to FALSE.
row.names, col.names	logical, should the name of rows and/or columns of <code>mat</code> be shown? If TRUE (defaults) <code>rownames(mat)</code> and/or <code>colnames(mat)</code> are used. Possible character vectors with row and/or column labels can be used.
size.legend	size of the legend

Details

This function is a small wrapper of `link{cim}` specific to the DIABLO framework.

Value

none

  scheme = "centroid")

cimDiablo(nutrimouse.sgccda)
```

circosPlot

circosPlot for DIABLO

Description

Displays variable correlation among different blocks

Usage

```
circosPlot(object,
  comp = 1 : min(object$ncomp),
  cutoff,
  color.Y,
  color.blocks,
  color.cor,
  var.names = NULL,
  showIntraLinks = FALSE,
  line = TRUE,
  size.legend = 0.8,
  ncol.legend = 1,
  size.variables = 0.25,
```

```
size.labels = 1,
legend = TRUE)
```

Arguments

<code>object</code>	An object of class inheriting from "block.splsda".
<code>comp</code>	Numeric vector indicating which component to plot. Default to all
<code>cutoff</code>	Only shows links with a correlation higher than cutoff
<code>color.Y</code>	a character vector of colors to be used for the levels of the outcome
<code>color.blocks</code>	a character vector of colors to be used for the blocks
<code>color.cor</code>	a character vector of two colors. First one is for the negative correlation, second one is for the positive correlation
<code>var.names</code>	Optional parameter. A list of length the number of blocks in <code>object\$X</code> , containing the names of the variables of each block. If NULL, the colnames of the data matrix are used.
<code>showIntraLinks</code>	if TRUE, shows the correlation higher than the threshold inside each block.
<code>line</code>	if TRUE, shows the overall expression of the selected variables. see examples.
<code>size.legend</code>	size of the legend
<code>ncol.legend</code>	number of columns for the legend
<code>size.variables</code>	size of the variable labels
<code>size.labels</code>	size of the block labels
<code>legend</code>	boolean. Whether the legend should be added. Default is TRUE.

Details

`circosPlot` function depicts correlations of variables selected with `block.splsda` among different blocks, using a generalisation of the method presented in González et al 2012. If `ncomp` is specified, then only the variables selected on that component are displayed.

Value

If saved in an object, the `circos` plot will output the similarity matrix and the names of the variables displayed on the plot (see `attributes(object)`).

```

color.jet

Color Palette for mixOmics

Description

The functions create a vector of n "contiguous" colors (except the color.mixo which are colors used internally to fit our logo colors).

Usage

```

color.jet(n, alpha = 1)
color.spectral(n, alpha = 1)
color.GreenRed(n, alpha = 1)
color.mixo(num.vector)

```

Arguments

n	an integer, the number of colors (≥ 1) to be in the palette.
alpha	a numeric value between 0 and 1 for alpha channel (opacity).
num.vector	for <code>color.mixo</code> an integer vector specifying which colors to use in the mixOmics palette (there are only 10 colors available).

Details

The function `color.jet(n)` create color scheme, beginning with dark blue, ranging through shades of blue, cyan, green, yellow and red, and ending with dark red. This colors palette is suitable for displaying ordered (symmetric) data, with `n` giving the number of colors desired.

Value

For `color.jet(n)`, `color.spectral(n)`, `color.GreenRed(n)` a character vector, `cv`, of color names. This can be used either to create a user-defined color palette for subsequent graphics by `palette(cv)`, a `col=` specification in graphics functions or in `par`.

For `color.mixo`, a vector of colors matching the mixOmics logo (10 colors max.)

diverse.16S

*16S microbiome data: most diverse bodysites from HMP***Description**

The 16S data from the Human Microbiome Project includes only the most diverse bodysites: Antecubital fossa (skin), Stool and Subgingival plaque (oral) and can be analysed using a multilevel approach to account for repeated measurements using our module mixMC. The data include 162 samples (54 unique healthy individuals) measured on 1,674 OTUs.

Usage

```
data(diverse.16S)
```

Format

A list containing two data sets, `data.TSS` and `data.raw` and some meta data information:

`data.TSS` data frame with 162 rows (samples) and 1674 columns (OTUs). The prefiltered normalised data using Total Sum Scaling normalisation.

`data.raw` data frame with 162 rows (samples) and 1674 columns (OTUs). The prefiltered raw count OTU data which include a 1 offset (i.e. no 0 values).

`taxonomy` data frame with 1674 rows (OTUs) and 6 columns indicating the taxonomy of each OTU.

`indiv` data frame with 162 rows indicating sample meta data.

`bodysite` factor of length 162 indicating the bodysite with levels "Antecubital_fossa", "Stool" and "Subgingival_plaque".

`sample` vector of length 162 indicating the unique individual ID, useful for a multilevel approach to taken into account the repeated measured on each individual.

Details

The data were downloaded from the Human Microbiome Project (HMP, <http://hmpdacc.org/HMQCP/all/> for the V1-3 variable region). The original data contained 43,146 OTU counts for 2,911 samples measured from 18 different body sites. We focused on the first visit of each healthy individual and focused on the three most diverse habitats. The prefiltered dataset included 1,674 OTU counts. We strongly recommend to use log ratio transformations on the data.TSS normalised data, as implemented in the PLS and PCA methods, see details on www.mixOmicS.org/mixMC.

The data.raw include a 1 offset in order to be log ratios transformed after TSS normalisation. Consequently, the data.TSS are TSS normalisation of data.raw. The CSS normalisation was performed on the original data (including zero values)

Value

none

Source

The raw data were downloaded from <http://hmpdacc.org/HMQCP/all/>. Filtering and normalisation described in our website www.mixOmicS.org/mixMC

References

estim.regul

Estimate the parameters of regularization for Regularized CCA

Description

This function has been renamed `tune.rcc`, see [tune.rcc](#).

Value

none

explained_variance

Calculation of explained variance

Description

This function calculates the variance explained by variates.

Usage

```
explained_variance(data, variates, ncomp)
```

Arguments

data numeric matrix of predictors
variates variates as obtained from a pls object for instance
ncomp number of components. Should be lower than the number of columns of variates

Details

explained_variance calculates the explained variance of each variates out of the total variance in data.

Value

explained_variance simply returns the explained variance for each variate.

Author(s)

Florian Rohart

Examples

```
data(liver.toxicity)
X <- liver.toxicity$gene
Y <- liver.toxicity$clinic

toxicity.spls <- spls(X, Y, ncomp = 2, keepX = c(50, 50), keepY = c(10, 10))

ex = explained_variance(toxicity.spls$X, toxicity.spls$variates$X, ncomp =2)

# ex should be the same as
toxicity.spls$explained_variance$X
```

get.confusion_matrix *Create confusion table and calculate the Balanced Error Rate*

Description

Create confusion table between a vector of true classes and a vector of predicted classes, calculate the Balanced Error rate

Usage

```
get.confusion_matrix(truth, all.levels, predicted)

get.BER(confusion)
```

Arguments

<code>truth</code>	A factor vector indicating the true classes of the samples (typically Y from the training set).
<code>all.levels</code>	Levels of the 'truth' factor. Optional parameter if there are some missing levels in <code>truth</code> compared to the fitted predicted model
<code>predicted</code>	Vector of predicted classes (typically the prediction from the test set). Can contain NA.
<code>confusion</code>	result from a <code>get.confusion_matrix</code> to calculate the Balanced Error Rate

Details

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

Value

`get.confusion_matrix` returns a confusion matrix.
`get.BER` returns the BER from a confusion matrix

```

```
# the confusion table compares the real subtypes with the predicted subtypes for a 2 component model
confusion.mat = get.confusion_matrix(truth = Y[test],
predicted = Prediction)

get.BER(confusion.mat)
```

image

Plot the cross-validation score.

Description

This function provide a image map (checkerboard plot) of the cross-validation score obtained by the `tune.rcc` function.

Usage

```
## S3 method for class 'tune.rcc'
plot(x, col = heat.colors, ...)
```

```
## S3 method for class 'tune.rcc'
image(x, col = heat.colors, ...)
```

Arguments

x	object returned by <code>tune.rcc</code> .
col	a character string specifying the colors function to use: terrain.colors , topo.colors , rainbow or similar functions. Defaults to heat.colors .
...	not used currently.

Details

`plot.tune.rcc` creates an image map of the matrix `object$mat` containing the cross-validation score obtained by the `tune.rcc` function. Also a color scales strip is plotted.

Value

none

Author(s)

Sébastien Déjean and Ignacio González.

none

```

imgCor                  Image Maps of Correlation Matrices between two Data Sets

```

Description

Display two-dimensional visualizations (image maps) of the correlation matrices within and between two data sets.

Usage

```

imgCor(X,
Y,
type = "combine",
X.var.names = TRUE,
Y.var.names = TRUE,
sideColors = TRUE,
interactive.dev = TRUE,
title = TRUE,
color, row.cex, col.cex, symkey, keysize,
xlab, ylab, margins, lhei, lwid)

```

Arguments

<code>X</code>	numeric matrix or data frame ($n \times p$), the observations on the X variables. NAs are allowed.
<code>Y</code>	numeric matrix or data frame ($n \times q$), the observations on the Y variables. NAs are allowed.
<code>type</code>	character string, (partially) matching one of "combine" or "separated", determining the kind of plots to be produced. See Details.
<code>X.var.names</code> , <code>Y.var.names</code>	logical, should the name of X - and/or Y -variables be shown? If TRUE (defaults) <code>object\$names\$X</code> and/or <code>object\$names\$Y</code> are used. Possible character vector with X - and/or Y -variable labels to use.
<code>sideColors</code>	character vector of length two. The color name for horizontal and vertical side bars that may be used to annotate the X and Y correlation matrices.
<code>interactive.dev</code>	boolean. The current graphics device that will be opened is interactive?
<code>title</code>	logical, should the main titles be shown?
<code>color</code> , <code>xlab</code> , <code>ylab</code>	arguments passed to <code>cim</code> .
<code>row.cex</code> , <code>col.cex</code>	positive numbers, used as <code>cex.axis</code> in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.
<code>symkey</code>	boolean indicating whether the color key should be made symmetric about 0. Defaults to TRUE.
<code>keysize</code>	positive numeric value indicating the size of the color key.
<code>margins</code>	numeric vector of length two containing the margins (see <code>par(mar)</code>) for column and row names respectively.
<code>lhei</code> , <code>lwid</code>	arguments passed to <code>layout</code> to divide the device up into two rows and two columns, with the row-heights <code>lhei</code> and the column-widths <code>lwid</code> .

Details

If `type="combine"`, the correlation matrix is computed of the combined matrices `cbind(X, Y)` and then plotted. If `type="separate"`, three correlation matrices are computed, `cor(X)`, `cor(Y)` and `cor(X, Y)` and plotted separately on a device. In both cases, a color correlation scales strip is plotted.

The correlation matrices are pre-processed before calling the `image` function in order to get, as in the numerical representation, the diagonal from upper-left corner to bottom-right one.

Missing values are handled by casewise deletion in the `imgCor` function.

If `X.names = FALSE`, the name of each X -variable is hidden. Default value is TRUE.

If `Y.names = FALSE`, the name of each Y -variable is hidden. Default value is TRUE.

Value

none

ipca

Independent Principal Component Analysis

Description

Performs independent principal component analysis on the given data matrix, a combination of Principal Component Analysis and Independent Component Analysis.

Usage

```
ipca(X,
     ncomp = 2,
     mode = "deflation",
     fun = "logcosh",
     scale = FALSE,
     w.init = NULL,
     max.iter = 200,
     tol = 1e-04)
```

Arguments

X	a numeric matrix (or data frame) which provides the data for the principal component analysis.
ncomp	integer, number of independent component to choose. Set by default to 3.
mode	character string. What type of algorithm to use when estimating the unmixing matrix, choose one of "deflation", "parallel". Default set to deflation.
fun	the function used in approximation to neg-entropy in the FastICA algorithm. Default set to logcosh, see details of FastICA.

scale	a logical value indicating whether the variables (columns) of the data matrix X should be standardized beforehand. By default, X is centered.
max.iter	integer, maximum number of iterations to perform.
tol	a positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged, see fastICA package.
w.init	initial un-mixing matrix (unlike FastICA, this matrix is fixed here).

Details

In PCA, the loading vectors indicate the importance of the variables in the principal components. In large biological data sets, the loading vectors should only assign large weights to important variables (genes, metabolites ...). That means the distribution of any loading vector should be super-Gaussian: most of the weights are very close to zero while only a few have large (absolute) values.

However, due to the existence of noise, the distribution of any loading vector is distorted and tends toward a Gaussian distribution according to the Central Limit Theorem. By maximizing the non-Gaussianity of the loading vectors using FastICA, we obtain more noiseless loading vectors. We then project the original data matrix on these noiseless loading vectors, to obtain independent principal components, which should be also more noiseless and be able to better cluster the samples according to the biological treatment (note, IPCA is an unsupervised approach).

Algorithm 1. The original data matrix is centered.

2. PCA is used to reduce dimension and generate the loading vectors.
3. ICA (FastICA) is implemented on the loading vectors to generate independent loading vectors.
4. The centered data matrix is projected on the independent loading vectors to obtain the independent principal components.

Value

ipca returns a list with class "ipca" containing the following components:

ncomp	the number of independent principal components used.
unmixing	the unmixing matrix of size (ncomp x ncomp)
mixing	the mixing matrix of size (ncomp x ncomp)
X	the centered data matrix
x	the independent principal components
loadings	the independent loading vectors
kurtosis	the kurtosis measure of the independent loading vectors

Koren.16S

16S microbiome atherosclerosis study

Description

The 16S data come from Koren et al. (2011) and compared the bodysites oral, gut and plaque microbial communities in patients with atherosclerosis. The data can be analysed with our mixMC module. The data include 43 samples measured on 980 OTUs.

Usage

```
data(Koren.16S)
```

Format

A list containing two data sets, `data.TSS` and `data.raw` and some meta data information:

`data.TSS` data frame with 43 rows (samples) and 980 columns (OTUs). The prefiltered normalised data using Total Sum Scaling normalisation.

`data.raw` data frame with 43 rows (samples) and 980 columns (OTUs). The prefiltered raw count OTU data which include a 1 offset (i.e. no 0 values).

`taxonomy` data frame with 980 rows (OTUs) and 7 columns indicating the taxonomy of each OTU.

`indiv` data frame with 43 rows indicating sample meta data.

`bodysite` factor of length 43 indicating the bodysite with levels arterial plaque, saliva and stool.

Details

The data are from Koren et al. (2011) who examined the link between oral, gut and plaque microbial communities in patients with atherosclerosis and controls. Only healthy individuals were retained in the analysis. This study contained partially repeated measures from multiple sites including 15 unique patients samples from saliva and stool, and 13 unique patients only sampled from arterial plaque samples and we therefore considered a non multilevel analysis for that experimental design. After prefiltering, the data included 973 OTU for 43 samples. We strongly recommend to use log ratio transformations on the data. TSS normalised data, as implemented in the PLS and PCA methods, see details on www.mixOmicS.org/mixMC.

The data.raw include a 1 offset in order to be log ratios transformed after TSS normalisation. Consequently, the data.TSS are TSS normalisation of data.raw. The CSS normalisation was performed on the original data (including zero values)

Value

none

Source

The raw data were downloaded from the QIITA database. Filtering and normalisation described in our website www.mixOmicS.org/mixMC

linnerud

Linnerud Dataset

Description

Three physiological and three exercise variables are measured on twenty middle-aged men in a fitness club.

Usage

```
data(linnerud)
```

Format

A list containing the following components:

exercise data frame with 20 observations on 3 exercise variables.

physiological data frame with 20 observations on 3 physiological variables.

Value

none

liver.toxicity	<i>Liver Toxicity Data</i>
----------------	----------------------------

Description

This data set contains the expression measure of 3116 genes and 10 clinical measurements for 64 subjects (rats) that were exposed to non-toxic, moderately toxic or severely toxic doses of acetaminophen in a controlled experiment.

Usage

```
data(liver.toxicity)
```

Format

A list containing the following components:

gene data frame with 64 rows and 3116 columns. The expression measure of 3116 genes for the 64 subjects (rats).

clinic data frame with 64 rows and 10 columns, containing 10 clinical variables for the same 64 subjects.

treatment data frame with 64 rows and 4 columns, containing the treatment information on the 64 subjects, such as doses of acetaminophen and times of necropsies.

gene.ID data frame with 3116 rows and 2 columns, containing geneBank IDs and gene titles of the annotated genes

Details

The data come from a liver toxicity study (Bushel *et al.*, 2007) in which 64 male rats of the inbred strain Fisher 344 were exposed to non-toxic (50 or 150 mg/kg), moderately toxic (1500 mg/kg) or severely toxic (2000 mg/kg) doses of acetaminophen (paracetamol) in a controlled experiment. Necropsies were performed at 6, 18, 24 and 48 hours after exposure and the mRNA from the liver was extracted. Ten clinical chemistry measurements of variables containing markers for liver injury are available for each subject and the serum enzymes levels are measured numerically. The data were further normalized and pre-processed by Bushel *et al.* (2007).

Value

none

Source

The two liver toxicity data sets are a companion resource for the paper of Bushel *et al.* (2007), and was downloaded from:

<http://www.biomedcentral.com/1752-0509/1/15/additional/>

logratio.transfo	<i>Log-ratio transformation</i>
------------------	---------------------------------

Description

This function applies a log transformation to the data, either CLR or ILR

Usage

```
logratio.transfo(X, logratio = "none", offset = 0)
```

Arguments

X	numeric matrix of predictors
logratio	log-ratio transform to apply, one of "none", "CLR" or "ILR"
offset	Value that is added to X for CLR and ILR log transformation. Default to 0.

Details

logratio.transfo applies a log transformation to the data, either CLR (centered log ratio transformation) or ILR (Isometric Log Ratio transformation). In the case of CLR log-transformation, X needs to be a matrix of non-negative values and offset is used to shift the values away from 0, as commonly done with counts data.

Value

logratio.transfo simply returns the log-ratio transformed data.

```

map

Classification given Probabilities

Description

Converts a matrix in which each row sums to 1 into the nearest matrix of $(0,1)$ indicator variables.

Usage

```
map(Y)
```

Arguments

Y A matrix (for example a matrix of conditional probabilities in which each row sums to 1).

Value

A integer vector with one entry for each row of Y, in which the i -th value is the column index at which the i -th row of Y attains a maximum.

```

`mat.rank`*Matrix Rank*

Description

This function estimate the rank of a matrix.

Usage

```
mat.rank(mat, tol)
```

Arguments

<code>mat</code>	a numeric matrix or data frame that can contain missing values.
<code>tol</code>	positive real, the tolerance for singular values, only those with values larger than <code>tol</code> are considered non-zero.

Details

`mat.rank` estimate the rank of a matrix by computing its singular values $d[i]$ (using `nipals`). The rank of the matrix can be defined as the number of singular values $d[i] > 0$.

If `tol` is missing, it is given by `tol=max(dim(mat))*max(d)*.Machine$double.eps`.

Value

The returned value is a list with components:

<code>rank</code>	a integer value, the matrix rank.
<code>tol</code>	the tolerance used for singular values.

Author(s)

Sébastien Déjean and Ignacio González.

## Not run:
## Hilbert matrix with missing data
idx.na <- matrix(sample(c(0, 1, 1, 1, 1), 36, replace = TRUE), ncol = 6)
m.na <- m <- hilbert(9)[, 1:6]
m.na[idx.na == 0] <- NA
mat.rank(m)
mat.rank(m.na)

## End(Not run)
```

mint.block.pls *NP-integration*

Description

Function to integrate data sets measured on the same samples (N-integration) and to combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of multi-group and generalised PLS (unsupervised analysis).

Usage

```
mint.block.pls(X,
  Y,
  indY,
  study,
  ncomp = 2,
  design,
  scheme,
  mode,
  scale = TRUE,
  init ,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE)
```

Arguments

X	A list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in samples x variables, with samples order matching in all data sets.
Y	Matrix or vector response for a multivariate regression framework. Data should be continuous variables (see mint.block.plsda for supervised classification and factor reponse)
indY	To be supplied if Y is missing, indicates the position of the matrix / vector response in the list X
study	factor indicating the membership of each sample to each of the studies being combined
ncomp	the number of components to include in the model. Default to 2.
design	numeric matrix of size (number of blocks) x (number of blocks) with only 0 or 1 values. A value of 1 (0) indicates a relationship (no relationship) between the blocks to be modelled. If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
scheme	Either "horst", "factorial" or "centroid". Default = horst, see reference.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)

<code>init</code>	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default = <code>svd.single</code> .
<code>tol</code>	Convergence stopping value.
<code>max.iter</code>	integer, the maximum number of iterations.
<code>near.zero.var</code>	boolean, see the internal <code>nearZeroVar</code> function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
<code>all.outputs</code>	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

The function fits multi-group generalised PLS models with a specified number of `ncomp` components. An outcome needs to be provided, either by Y or by its position `indY` in the list of blocks X .

Multi (continuous)response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm `block.pls` without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the `nipals` function.

The type of algorithm to use is specified with the `mode` argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and more details in `?pls`).

Value

`mint.block.pls` returns an object of class "`mint.pls`", "`block.pls`", a list that contains the following components:

<code>X</code>	the centered and standardized original predictor matrix.
<code>Y</code>	the centered and standardized original response vector or matrix.
<code>ncomp</code>	the number of components included in the model for each block.
<code>mode</code>	the algorithm used to fit the model.
<code>mat.c</code>	matrix of coefficients from the regression of X / residual matrices X on the X -variates, to be used internally by <code>predict</code> .
<code>variates</code>	list containing the X and Y variates.
<code>loadings</code>	list containing the estimated loadings for the variates.
<code>names</code>	list containing the names to be used for individuals and variables.
<code>nzv</code>	list containing the zero- or near-zero predictors information.
<code>tol</code>	the tolerance used in the iterative algorithm, used for subsequent S3 methods
<code>max.iter</code>	the maximum number of iterations, used for subsequent S3 methods
<code>iter</code>	Number of iterations of the algorithm for each component

res
```

mint.block.plsda

NP-integration with Discriminant Analysis

Description

Function to integrate data sets measured on the same samples (N-integration) and to combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of multi-group and generalised PLS-DA for supervised classification.

Usage

```
mint.block.plsda(X,
  Y,
  indY,
  study,
  ncomp = 2,
  design,
  scheme,
  mode,
  scale = TRUE,
  init ,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE)
```

Arguments

X	A list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in samples x variables, with samples order matching in all data sets.
Y	A factor or a class vector indicating the discrete outcome of each sample.
indY	To be supplied if Y is missing, indicates the position of the matrix / vector response in the list X
study	factor indicating the membership of each sample to each of the studies being combined
ncomp	Number of components to include in the model (see Details). Default to 2.
design	numeric matrix of size (number of blocks in X) x (number of blocks in X) with 0 or 1 values. A value of 1 (0) indicates a relationship (no relationship) between the blocks to be modelled. If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
scheme	Either "horst", "factorial" or "centroid". Default = horst, see reference.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
init	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default = svd.single.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

The function fits multi-group generalised PLS models with a specified number of `ncomp` components. A factor indicating the discrete outcome needs to be provided, either by `Y` or by its position `indY` in the list of blocks `X`.

`X` can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm `block.pls` without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the `nipals` function.

The type of algorithm to use is specified with the `mode` argument. Four PLS algorithms are available: PLS regression ("`regression`"), PLS canonical analysis ("`canonical`"), redundancy analysis ("`invariant`") and the classical PLS algorithm ("`classic`") (see References and more details in `?pls`).

Value

`mint.block.plsda` returns an object of class "`mint.plsda`", "`block.plsda`", a list that contains the following components:

<code>X</code>	the centered and standardized original predictor matrix.
<code>Y</code>	the centered and standardized original response vector or matrix.
<code>ncomp</code>	the number of components included in the model for each block.
<code>mode</code>	the algorithm used to fit the model.
<code>mat.c</code>	matrix of coefficients from the regression of <code>X</code> / residual matrices <code>X</code> on the <code>X</code> -variates, to be used internally by <code>predict</code> .
<code>variates</code>	list containing the <code>X</code> and <code>Y</code> variates.
<code>loadings</code>	list containing the estimated loadings for the variates.
<code>names</code>	list containing the names to be used for individuals and variables.
<code>nzv</code>	list containing the zero- or near-zero predictors information.
<code>tol</code>	the tolerance used in the iterative algorithm, used for subsequent S3 methods
<code>max.iter</code>	the maximum number of iterations, used for subsequent S3 methods
<code>iter</code>	Number of iterations of the algorithm for each component

mint.block.spls

NP-integration for integration with variable selection

Description

Function to integrate data sets measured on the same samples (N-integration) and to combine multiple independent studies (P-integration) using variants of sparse multi-group and generalised PLS with variable selection (unsupervised analysis).

Usage

```
mint.block.spls(X,
  Y,
  indY,
  study,
  ncomp = 2,
  keepX,
  keepY,
```

```

design,
scheme,
mode,
scale = TRUE,
init ,
tol = 1e-06,
max.iter = 100,
near.zero.var = FALSE,
all.outputs = TRUE)

```

Arguments

X	A list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in samples x variables, with samples order matching in all data sets.
Y	Matrix or vector response for a multivariate regression framework. Data should be continuous variables (see block.splsda for supervised classification and factor reponse)
indY	To supply if Y is missing, indicates the position of the matrix / vector response in the list X
study	factor indicating the membership of each sample to each of the studies being combined
ncomp	the number of components to include in the model. Default to 2.
keepX	A list of same length as X. Each entry is the number of variables to select in each of the blocks of X for each component. By default all variables are kept in the model.
keepY	Only if Y is provided. Each entry is the number of variables to select in each of the blocks of Y for each component. By default all variables are kept in the model.
design	numeric matrix of size (number of blocks in X) x (number of blocks in X) with 0 or 1 values. A value of 1 (0) indicates a relationship (no relationship) between the blocks to be modelled. If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
scheme	Either "horst", "factorial" or "centroid". Default = horst, see reference.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
init	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default = svd.single.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

The function fits sparse multi-group generalised PLS models with a specified number of `ncomp` components. An outcome needs to be provided, either by `Y` or by its position `indY` in the list of blocks `X`.

Multi (continuous) response are supported. `X` and `Y` can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm `block.pls` without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the `nipals` function.

The type of algorithm to use is specified with the `mode` argument. Four PLS algorithms are available: PLS regression ("`regression`"), PLS canonical analysis ("`canonical`"), redundancy analysis ("`invariant`") and the classical PLS algorithm ("`classic`") (see References and more details in `?pls`).

Value

`mint.block.pls` returns an object of class "`mint.pls`", "`block.pls`", a list that contains the following components:

<code>X</code>	the centered and standardized original predictor matrix.
<code>Y</code>	the centered and standardized original response vector or matrix.
<code>ncomp</code>	the number of components included in the model for each block.
<code>mode</code>	the algorithm used to fit the model.
<code>mat.c</code>	matrix of coefficients from the regression of <code>X</code> / residual matrices <code>X</code> on the <code>X</code> -variates, to be used internally by <code>predict</code> .
<code>variates</code>	list containing the <code>X</code> and <code>Y</code> variates.
<code>loadings</code>	list containing the estimated loadings for the variates.
<code>names</code>	list containing the names to be used for individuals and variables.
<code>nzv</code>	list containing the zero- or near-zero predictors information.
<code>tol</code>	the tolerance used in the iterative algorithm, used for subsequent S3 methods
<code>max.iter</code>	the maximum number of iterations, used for subsequent S3 methods
<code>iter</code>	Number of iterations of the algorithm for each component

Examples

```

data(breast.TCGA)

# for the purpose of this example, we create data that fit in the context of
# this function.
# We consider the training set as study1 and the test set as another
# independent study2.

study = c(rep("study1",150), rep("study2",70))

# to put the data in the MINT format, we rbind the two studies
mrna = rbind(breast.TCGA$data.train$mrna, breast.TCGA$data.test$mrna)
mirna = rbind(breast.TCGA$data.train$mirna, breast.TCGA$data.test$mirna)

# For the purpose of this example, we create a continuous response by
# taking the first mrna variable, and removing it from the data
Y = mrna[,1]
mrna = mrna[,-1]

data = list(mrna = mrna, mirna = mirna)

# we can now apply the function
res = mint.block.splsda(data, Y, study=study, ncomp=2,
keepX = list(mrna=c(10,10), mirna=c(20,20)))

res

```

mint.block.splsda *NP-integration with Discriminant Analysis and variable selection*

Description

Function to integrate data sets measured on the same samples (N-integration) and to combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of sparse multi-group and generalised PLS-DA for supervised classification and variable selection.

Usage

```

mint.block.splsda(X,
Y,
indY,
study,
ncomp = 2,
keepX,
design,
scheme,
mode,
scale = TRUE,
init ,
tol = 1e-06,
max.iter = 100,
near.zero.var = FALSE,

```

```
all.outputs = TRUE)
```

Arguments

X	A list of data sets (called 'blocks') measured on the same samples. Data in the list should be arranged in samples x variables, with samples order matching in all data sets.
Y	A factor or a class vector indicating the discrete outcome of each sample.
indY	To be supplied if Y is missing, indicates the position of the matrix / vector response in the list X
study	factor indicating the membership of each sample to each of the studies being combined
ncomp	Number of components to include in the model (see Details). Default to 2.
keepX	A list of same length as X. Each entry is the number of variables to select in each of the blocks of X for each component. By default all variables are kept in the model.
design	numeric matrix of size (number of blocks in X) x (number of blocks in X) with 0 or 1 values. A value of 1 (0) indicates a relationship (no relationship) between the blocks to be modelled. If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
scheme	Either "horst", "factorial" or "centroid". Default = horst, see reference.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
init	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default = svd.single.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

The function fits sparse multi-group generalised PLS Discriminant Analysis models with a specified number of ncomp components. A factor indicating the discrete outcome needs to be provided, either by Y or by its position indY in the list of blocks X.

X can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm block.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and more details in ?pls).

Value

mint.block.splsda returns an object of class "mint.splsda", "block.splsda", a list that contains the following components:

X	the centered and standardized original predictor matrix.
Y	the centered and standardized original response vector or matrix.
ncomp	the number of components included in the model for each block.
mode	the algorithm used to fit the model.
mat.c	matrix of coefficients from the regression of X / residual matrices X on the X-variates, to be used internally by predict.
variates	list containing the X and Y variates.
loadings	list containing the estimated loadings for the variates.
names	list containing the names to be used for individuals and variables.
nzv	list containing the zero- or near-zero predictors information.
tol	the tolerance used in the iterative algorithm, used for subsequent S3 methods
max.iter	the maximum number of iterations, used for subsequent S3 methods
iter	Number of iterations of the algorithm for each component

```

mint.pca

*P-integration with Principal Component Analysis***Description**

Function to integrate and combine multiple independent studies measured on the same variables or predictors (P-integration) using a multigroup Principal Component Analysis.

Usage

```

mint.pca(X,
ncomp = 2,
study,
scale = TRUE,
tol = 1e-06,
max.iter = 100
)

```

Arguments

X	numeric matrix of predictors combining multiple independent studies on the same set of predictors. NAs are allowed.
ncomp	Number of components to include in the model (see Details). Default to 2
study	factor indicating the membership of each sample to each of the studies being combined
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances. Default = TRUE.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.

Details

mint.pca fits a vertical PCA model with ncomp components in which several independent studies measured on the same variables are integrated. The study factor indicates the membership of each sample in each study. We advise to only combine studies with more than 3 samples as the function performs internal scaling per study.

Missing values are handled by being disregarded during the cross product computations in the algorithm without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

Useful graphical outputs are available, e.g. [plotIndiv](#), [plotLoadings](#), [plotVar](#).

Value

mint.pca returns an object of class "mint.pca", "pca", a list that contains the following components:

X	the centered and standardized original predictor matrix.
ncomp	the number of components included in the model.
study	The study grouping factor
sdev	the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix or by using NIPALS.
center, scale	the centering and scaling used, or FALSE.
rotation	the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors).
loadings	same as 'rotation' to keep the mixOmics spirit
x	the value of the rotated data (the centred (and scaled if requested) data multiplied by the rotation/loadings matrix), also called the principal components.
variates	same as 'x' to keep the mixOmics spirit
explained_variance	explained variance from the multivariate model, used for plotIndiv
names	list containing the names to be used for individuals and variables.

Examples

```

data(stemcells)

res = mint.pca(X = stemcells$gene, ncomp = 3,
              study = stemcells$study)

plotIndiv(res, group = stemcells$celltype, legend=TRUE)

```

mint.pls

*P-integration***Description**

Function to integrate and combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of multi-group PLS (unsupervised analysis).

Usage

```

mint.pls(X,
         Y,
         ncomp = 2,
         mode = c("regression", "canonical", "invariant", "classic"),
         study,
         scale = TRUE,
         tol = 1e-06,
         max.iter = 100,
         near.zero.var = FALSE,
         all.outputs = TRUE)

```

Arguments

X	numeric matrix of predictors combining multiple independent studies on the same set of predictors. NAs are allowed.
Y	Matrix or vector response for a multivariate regression framework. Data should be continuous variables (see <code>mint.plsda</code> for supervised classification and factor reponse)
ncomp	Number of components to include in the model (see Details). Default to 2
mode	character string. What type of algorithm to use, (partially) matching one of "regression" or "canonical". See Details.
study	factor indicating the membership of each sample to each of the studies being combined
scale	boolean. If <code>scale = TRUE</code> , each block is standardized to zero means and unit variances. Default = <code>TRUE</code> .
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal <code>nearZeroVar</code> function (should be set to <code>TRUE</code> in particular for data with many zero values). Default = <code>FALSE</code> .
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = <code>TRUE</code> .

Details

mint.pls fits a vertical PLS-DA models with ncomp components in which several independent studies measured on the same variables are integrated. The aim is to explain the continuous outcome Y. The study factor indicates the membership of each sample in each study. We advise to only combine studies with more than 3 samples as the function performs internal scaling per study.

Multi (continuous)response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm mint.pls without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the nipals function.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and more details in ?pls).

Useful graphical outputs are available, e.g. [plotIndiv](#), [plotLoadings](#), [plotVar](#).

Value

mint.pls returns an object of class "mint.pls", "pls", a list that contains the following components:

X	the centered and standardized original predictor matrix.
Y	the centered and standardized original response vector or matrix.
ncomp	the number of components included in the model.
study	The study grouping factor
mode	the algorithm used to fit the model.
variates	list containing the variates of X - global variates.
loadings	list containing the estimated loadings for the variates - global loadings.
variates.partial	list containing the variates of X relative to each study - partial variates.
loadings.partial	list containing the estimated loadings for the partial variates - partial loadings.
names	list containing the names to be used for individuals and variables.
nzv	list containing the zero- or near-zero predictors information.
iter	Number of iterations of the algorithm for each component
explained_variance	Percentage of explained variance for each component and each study (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between data sets).

<code>tol</code>	Convergence stopping value.
<code>max.iter</code>	integer, the maximum number of iterations.
<code>near.zero.var</code>	boolean, see the internal <code>nearZeroVar</code> function (should be set to <code>TRUE</code> in particular for data with many zero values). Default = <code>FALSE</code> .
<code>all.outputs</code>	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = <code>TRUE</code> .

Details

`mint.plsda` function fits a vertical PLS-DA models with `ncomp` components in which several independent studies measured on the same variables are integrated. The aim is to classify the discrete outcome `Y`. The `study` factor indicates the membership of each sample in each study. We advise to only combine studies with more than 3 samples as the function performs internal scaling per study, and where all outcome categories are represented.

`X` can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm `mint.plsda` without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the `nipals` function.

The type of algorithm to use is specified with the `mode` argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and more details in `?pls`).

Useful graphical outputs are available, e.g. `plotIndiv`, `plotLoadings`, `plotVar`.

Value

`mint.plsda` returns an object of class "`mint.plsda`", "`plsda`", a list that contains the following components:

<code>X</code>	the centered and standardized original predictor matrix.
<code>Y</code>	original factor
<code>ind.mat</code>	the centered and standardized original response vector or matrix.
<code>ncomp</code>	the number of components included in the model.
<code>study</code>	The study grouping factor
<code>mode</code>	the algorithm used to fit the model.
<code>variates</code>	list containing the variates of <code>X</code> - global variates.
<code>loadings</code>	list containing the estimated loadings for the variates - global loadings.
<code>variates.partial</code>	list containing the variates of <code>X</code> relative to each study - partial variates.
<code>loadings.partial</code>	list containing the estimated loadings for the partial variates - partial loadings.

names	list containing the names to be used for individuals and variables.
nzv	list containing the zero- or near-zero predictors information.
iter	Number of iterations of the algorithm for each component
explained_variance	Percentage of explained variance for each component and each study (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between X and the dummy matrix Y).

## End(Not run)
```

mint.spls

*P-integration with variable selection***Description**

Function to integrate and combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of multi-group sparse PLS for variable selection (unsupervised analysis).

Usage

```
mint.spls(X,
  Y,
  ncomp = 2,
  mode = c("regression", "canonical", "invariant", "classic"),
  study,
  keepX = rep(ncol(X), ncomp),
  keepY = rep(ncol(Y), ncomp),
  scale = TRUE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  all.outputs = TRUE)
```

Arguments

X	numeric matrix of predictors combining multiple independent studies on the same set of predictors. NAs are allowed.
Y	Matrix or vector response for a multivariate regression framework. Data should be continuous variables (see <code>mint.splsda</code> for supervised classification and factor response)
ncomp	Number of components to include in the model. Default to 2
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
study	grouping factor indicating which samples are from the same study
keepX	numeric vector indicating the number of variables to select in X on each component. By default all variables are kept in the model.
keepY	numeric vector indicating the number of variables to select in Y on each component. By default all variables are kept in the model.
scale	boolean. If <code>scale = TRUE</code> , each block is standardized to zero means and unit variances. Default = <code>TRUE</code> .
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal <code>nearZeroVar</code> function (should be set to <code>TRUE</code> in particular for data with many zero values). Default = <code>FALSE</code> .
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = <code>TRUE</code> .

Details

`mint.spls` fits a vertical sparse PLS-DA models with `ncomp` components in which several independent studies measured on the same variables are integrated. The aim is to explain the continuous outcome Y and selecting correlated features between both data sets X and Y . The study factor indicates the membership of each sample in each study. We advise to only combine studies with more than 3 samples as the function performs internal scaling per study.

Multi (continuous)response are supported. X and Y can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm `mint.spls` without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the `nipals` function.

The type of algorithm to use is specified with the `mode` argument. Four PLS algorithms are available: PLS regression ("`regression`"), PLS canonical analysis ("`canonical`"), redundancy analysis ("`invariant`") and the classical PLS algorithm ("`classic`") (see References and more details in `?pls`).

Variable selection is performed on each component for each block of X , and for Y if specified, via input parameter `keepX` and `keepY`.

Useful graphical outputs are available, e.g. `plotIndiv`, `plotLoadings`, `plotVar`.

Value

`mint.spls` returns an object of class "`mint.spls`", "`spls`", a list that contains the following components:

<code>X</code>	numeric matrix of predictors combining multiple independent studies on the same set of predictors. NAs are allowed.
<code>Y</code>	the centered and standardized original response vector or matrix.
<code>ncomp</code>	the number of components included in the model.
<code>study</code>	The study grouping factor
<code>mode</code>	the algorithm used to fit the model.
<code>keepX</code>	Number of variables used to build each component of X
<code>keepY</code>	Number of variables used to build each component of Y
<code>variates</code>	list containing the variates of X - global variates.
<code>loadings</code>	list containing the estimated loadings for the variates - global loadings.
<code>variates.partial</code>	list containing the variates of X relative to each study - partial variates.
<code>loadings.partial</code>	list containing the estimated loadings for the partial variates - partial loadings.
<code>names</code>	list containing the names to be used for individuals and variables.
<code>nzv</code>	list containing the zero- or near-zero predictors information.
<code>iter</code>	Number of iterations of the algorithm for each component
<code>explained_variance</code>	Percentage of explained variance for each component and each study (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between data sets).

mint.splsda

P-integration with Discriminant Analysis and variable selection

Description

Function to combine multiple independent studies measured on the same variables or predictors (P-integration) using variants of multi-group sparse PLS-DA for supervised classification with variable selection.

Usage

```
mint.splsda(X,
Y,
ncomp = 2,
mode = c("regression", "canonical", "invariant", "classic"),
study,
keepX = rep(ncol(X), ncomp),
scale = TRUE,
tol = 1e-06,
```

```
max.iter = 100,
near.zero.var = FALSE,
all.outputs = TRUE)
```

Arguments

X	numeric matrix of predictors combining multiple independent studies on the same set of predictors. NAs are allowed.
Y	A factor or a class vector indicating the discrete outcome of each sample.
ncomp	Number of components to include in the model (see Details). Default to 2
mode	character string. What type of algorithm to use, (partially) matching one of "regression" or "canonical". See Details.
study	factor indicating the membership of each sample to each of the studies being combined
keepX	numeric vector indicating the number of variables to select in X on each component. By default all variables are kept in the model.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances. Default = TRUE.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default = FALSE.
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

`mint.splsda` function fits a vertical sparse PLS-DA models with `ncomp` components in which several independent studies measured on the same variables are integrated. The aim is to classify the discrete outcome Y and select variables that explain the outcome. The `study` factor indicates the membership of each sample in each study. We advise to only combine studies with more than 3 samples as the function performs internal scaling per study, and where all outcome categories are represented.

X can contain missing values. Missing values are handled by being disregarded during the cross product computations in the algorithm `mint.splsda` without having to delete rows with missing data. Alternatively, missing data can be imputed prior using the `nipals` function.

The type of algorithm to use is specified with the `mode` argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and more details in `?pls`).

Variable selection is performed on each component for X via input parameter `keepX`.

Useful graphical outputs are available, e.g. [plotIndiv](#), [plotLoadings](#), [plotVar](#).

Value

`mint.splsda` returns an object of class "`mint.splsda`", "`splsda`", a list that contains the following components:

X	the centered and standardized original predictor matrix.
Y	the centered and standardized original response vector or matrix.
ind.mat	the centered and standardized original response vector or matrix.
ncomp	the number of components included in the model.
study	The study grouping factor
mode	the algorithm used to fit the model.
keepX	Number of variables used to build each component of X
variates	list containing the variates of X - global variates.
loadings	list containing the estimated loadings for the variates - global loadings.
variates.partial	list containing the variates of X relative to each study - partial variates.
loadings.partial	list containing the estimated loadings for the partial variates - partial loadings.
names	list containing the names to be used for individuals and variables.
nzv	list containing the zero- or near-zero predictors information.
iter	Number of iterations of the algorithm for each component
explained_variance	Percentage of explained variance for each component and each study (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between X and the dummy matrix Y).

mixOmics

PLS-derived methods: one function to rule them all!

Description

This function performs one of the PLS derived methods included in the mixOmics package that is the most appropriate for your input data, one of (mint).(block).(s)pls(da) depending on your input data (single data, list of data, discrete outcome, ...)

Usage

```

mixOmics(X,
Y,
indY,
study,
ncomp,
keepX,
keepY,
design,
tau = NULL, # rgcca, number between 0,1 or "optimal"
scheme,
mode,
scale,
init,
tol = 1e-06,
max.iter = 100,
near.zero.var = FALSE)

```

Arguments

X	Input data. Either a matrix or a list of data sets (called 'blocks') matching on the same samples. Data should be arranged in samples x variables, with samples order matching in all data sets.
Y	Outcome. Either a numeric matrix of responses or a factor or a class vector for the discrete outcome.
indY	To supply if Y is missing, indicates the position of the outcome in the list X
study	grouping factor indicating which samples are from the same study

ncomp	If X is a data matrix, ncomp is a single value. If X is a list of data sets, ncomp is a numeric vector of length the number of blocks in X. The number of components to include in the model for each block (does not necessarily need to take the same value for each block).
keepX	Number of variables to keep in the X-loadings
keepY	Number of variables to keep in the Y-loadings
design	numeric matrix of size (number of blocks) x (number of blocks) with only 0 or 1 values. A value of 1 (0) indicates a relationship (no relationship) between the blocks to be modelled. If Y is provided instead of indY, the design matrix is changed to include relationships to Y.
tau	numeric vector of length the number of blocks in X. Each regularization parameter will be applied on each block and takes the value between 0 (no regularization) and 1. If tau = "optimal" the shrinkage parameters are estimated for each block and each dimension using the Schafer and Strimmer (2005) analytical formula.
scheme	Either "horst", "factorial" or "centroid" (Default: "centroid"), see reference paper.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
init	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default to "svd".
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE

Details

This function performs one of the PLS derived methods included in the mixOmics package that is the most appropriate for your input data, one of (mint).(block).(s)pls(da).

If your input data X is a matrix, then the algorithm is directed towards one of (mint).(s)pls(da) depending on your input data Y (factor for the discrete outcome directs the algorithm to DA analysis) and whether you input a study parameter (MINT analysis) or a keepX parameter (sparse analysis).

If your input data X is a list of matrices, then the algorithm is directed towards one of (mint).block.(s)pls(da) depending on your input data Y (factor for the discrete outcome directs the algorithm to DA analysis) and whether you input a study parameter (MINT analysis) or a keepX parameter (sparse analysis).

More details about the PLS modes in ?pls.

multidrug

Multidrug Resistance Data

Description

This data set contains the expression of 48 known human ABC transporters with patterns of drug activity in 60 diverse cancer cell lines (the NCI-60) used by the National Cancer Institute to screen for anticancer activity.

Usage

```
data(multidrug)
```

Format

A list containing the following components:

`ABC.trans` data matrix with 60 rows and 48 columns. The expression of the 48 human ABC transporters.

`compound` data matrix with 60 rows and 1429 columns. The activity of 1429 drugs for the 60 cell lines.

`comp.name` character vector. The names or the NSC No. of the 1429 compounds.

`cell.line` a list containing two character vector components: `Sample` the names of the 60 cell line which were analysed, and `Class` the phenotypes of the 60 cell lines.

Details

The data come from a pharmacogenomic study (Szakacs *et al.*, 2004) in which two kinds of measurements acquired on the NCI-60 cancer cell lines are considered:

- the expression of the 48 human ABC transporters measured by real-time quantitative RT-PCR for each cell line;
- the activity of 1429 drugs expressed as GI_{50} which corresponds to the concentration at which the drug induces 50% inhibition of cellular growth for the cell line tested.

The NCI- 60 panel includes cell lines derived from cancers of colorectal (7 cell lines), renal(8), ovarian(6), breast(8), prostate(2), lung(9) and central nervous system origin(6), as well as leukemias(6) and melanomas(8). It was set up by the Developmental Therapeutics Program of the National Cancer Institute (NCI, one of the U.S. National Institutes of Health) to screen the toxicity of chemical compound repositories. The expressions of the 48 human ABC transporters is available as a supplement to the paper of Szakacs *et al.* (2004).

The drug dataset consists of 118 compounds whose mechanisms of action are putatively classifiable (Weinstein *et al.*, 1992) and a larger set of 1400 compounds that have been tested multiple times and whose screening data met quality control criteria described elsewhere (Scherf *et al.*, 2000). The two were combined to form a joint dataset that included 1429 compounds.

Value

none

Source

The NCI dataset was downloaded from The Genomics and Bioinformatics Group Supplemental Table S1 to the paper of Szakacs *et al.* (2004), http://discover.nci.nih.gov/abc/2004_cancer_cell_abstract.jsp#supplement

The two drug data sets are a companion resource for the paper of Scherf *et al.* (2000), and was downloaded from <http://discover.nci.nih.gov/datasetsNature2000.jsp>.

nearZeroVar

Identification of zero- or near-zero variance predictors

Description

Borrowed from the **caret** package. It is used as an internal function in the PLS methods, but can also be used as an external function, in particular when the data contain a lot of zero values and need to be prefiltered beforehand.

This function diagnoses predictors that have one unique value (i.e. are zero variance predictors) or predictors that have both of the following characteristics: they have very few unique values relative to the number of samples and the ratio of the frequency of the most common value to the frequency of the second most common value is large.

Usage

```
nearZeroVar(x, freqCut = 95/5, uniqueCut = 10)
```

Arguments

x	a numeric vector or matrix, or a data frame with all numeric data.
freqCut	the cutoff for the ratio of the most common value to the second most common value.
uniqueCut	the cutoff for the percentage of distinct values out of the number of total samples.

Details

For example, an example of near zero variance predictor is one that, for 1000 samples, has two distinct values and 999 of them are a single value.

To be flagged, first the frequency of the most prevalent value over the second most frequent value (called the “frequency ratio”) must be above `freqCut`. Secondly, the “percent of unique values,” the number of unique values divided by the total number of samples (times 100), must also be below `uniqueCut`.

In the above example, the frequency ratio is 999 and the unique value percentage is 0.0001.

Value

`nearZeroVar` returns a list that contains the following components:

Position	a vector of integers corresponding to the column positions of the problematic predictors that will need to be removed.
Metrics	a data frame containing the zero- or near-zero predictors information with columns: <code>freqRatio</code> , the ratio of frequencies for the most common value over the second most common value and, <code>percentUnique</code> , the percentage of unique data points out of the total number of data points.

Author(s)

```

network

*Relevance Network for (r)CCA and (s)PLS regression***Description**

Display relevance associations network for (regularized) canonical correlation analysis and (sparse) PLS regression. The function avoids the intensive computation of Pearson correlation matrices on large data set by calculating instead a pair-wise similarity matrix directly obtained from the latent components of our integrative approaches (CCA, PLS, block.pls methods). The similarity value between a pair of variables is obtained by calculating the sum of the correlations between the original variables and each of the latent components of the model. The values in the similarity matrix can be seen as a robust approximation of the Pearson correlation (see González et al. 2012 for a mathematical demonstration and exact formula). The advantage of relevance networks is their ability to simultaneously represent positive and negative correlations, which are missed by methods based on Euclidean distances or mutual information. Those networks are bipartite and thus only a link between two variables of different types can be represented. The network can be saved in a .glm format using the `igraph` package, the function `write.graph` and extracting the output object `$gR`, see details.

Usage

```
network(mat,
  comp = NULL,
  blocks = c(1,2),
  cutoff = NULL,
  row.names = TRUE,
  col.names = TRUE,
  block.var.names = TRUE,
  color.node = NULL,
  shape.node = NULL,
  cex.node.name = 1,
  color.edge = color.GreenRed(100),
  lty.edge = "solid",
  lwd.edge = 1,
  show.edge.labels = FALSE,
  cex.edge.label = 1,
  show.color.key = TRUE,
  symkey = TRUE,
  keysize = c(1, 1),
  keysize.label = 1,
  breaks,
  interactive = FALSE,
  layout.fun = NULL,
  save = NULL,
  name.save = NULL)
```

Arguments

<code>mat</code>	numeric matrix of values to be represented.
<code>comp</code>	atomic or vector of positive integers. The components to adequately account for the data association. Defaults to <code>comp = 1</code> .

<code>cutoff</code>	numeric value between 0 and 1. The tuning threshold for the relevant associations network (see Details).
<code>row.names, col.names</code>	character vector containing the names of X - and Y -variables.
<code>color.node</code>	vector of length two, the colors of the X and Y nodes (see Details).
<code>shape.node</code>	character vector of length two, the shape of the X and Y nodes (see Details).
<code>color.edge</code>	vector of colors or character string specifying the colors function to using to color the edges, set to default to <code>color.GreenRed(100)</code> but other palettes can be chosen (see Details and Examples).
<code>lty.edge</code>	character vector of length two, the line type for the edges (see Details).
<code>lwd.edge</code>	vector of length two, the line width of the edges (see Details).
<code>show.edge.labels</code>	logical. If TRUE, plot association values as edge labels (defaults to FALSE).
<code>show.color.key</code>	boolean. If TRUE a color key should be plotted.
<code>symkey</code>	boolean indicating whether the color key should be made symmetric about 0. Defaults to TRUE.
<code>keysize</code>	numeric value indicating the size of the color key.
<code>keysize.label</code>	vector of length 1, indicating the size of the labels and title of the color key.
<code>breaks</code>	(optional) either a numeric vector indicating the splitting points for binning <code>mat</code> into colors, or a integer number of break points to be used, in which case the break points will be spaced equally between <code>min(mat)</code> and <code>max(mat)</code> .
<code>interactive</code>	logical. If TRUE, a scrollbar is created to change the cutoff value interactively (defaults to FALSE). See Details.
<code>save</code>	should the plot be saved ? If so, argument to be set either to 'jpeg', 'tiff', 'png' or 'pdf'.
<code>name.save</code>	character string giving the name of the saved file.
<code>cex.edge.label</code>	the font size for the edge labels.
<code>cex.node.name</code>	the font size for the node labels.
<code>blocks</code>	a vector indicating the block variables to display.
<code>block.var.names</code>	either a list of vector components for variable names in each block or FALSE for no names. If TRUE, the columns names of the blocks are used as names.
<code>layout.fun</code>	a function. It specifies how the vertices will be placed on the graph. See <code>help(layout)</code> in the <code>igraph</code> package. Defaults to <code>layout.fruchterman.reingold</code> .

Details

`network` allows to infer large-scale association networks between the X and Y datasets in `rcc` or `spls`. The output is a graph where each X - and Y -variable corresponds to a node and the edges included in the graph portray associations between them.

In `rcc`, to identify X - Y pairs showing relevant associations, `network` calculate a similarity measure between X and Y variables in a pair-wise manner: the scalar product value between every pairs of vectors in dimension `length(comp)` representing the variables X and Y on the axis defined by Z_i with i in `comp`, where Z_i is the equiangular vector between the i -th X and Y canonical variate.

In `spls`, if `object$mode` is `regression`, the similarity measure between X and Y variables is given by the scalar product value between every pairs of vectors in dimension `length(comp)` representing

the variables X and Y on the axis defined by U_i with i in comp, where U_i is the i -th X variate. If `object$mode` is canonical then X and Y are represented on the axis defined by U_i and V_i respectively.

Variable pairs with a high similarity measure (in absolute value) are considered as relevant. By changing the cutoff, one can tune the relevance of the associations to include or exclude relationships in the network.

`interactive=TRUE` open two device, one for association network, one for scrollbar, and define an interactive process: by clicking either at each end ('-' or '+') of the scrollbar or at middle portion of this. The position of the slider indicate which is the 'cutoff' value associated to the display network.

The network can be saved in a `.glm` format using the **igraph** package, the function `write.graph` and extracting the output object `$gR`.

The interactive process is terminated by clicking the second button and selecting 'Stop' from the menu, or from the 'Stop' menu on the graphics window.

`color.node` is a vector of length two, of any of the three kind of R colors, i.e., either a color name (an element of `colors()`), a hexadecimal string of the form `"#rrggbb"`, or an integer `i` meaning `palette()[i]`. `color.node[1]` and `color.node[2]` give the color for filled nodes of the X - and Y -variables respectively. Defaults to `c("white", "white")`.

`color.edge` give the color to edges with colors corresponding to the values in `mat`. Defaults to `color.GreenRed(100)` for negative (green) and positive (red) correlations. We also propose other palettes of colors, such as `color.jet` and `color.spectral`, see help on those functions, and examples below. Other palette of colors from the `stats` package can be used too.

`shape.node[1]` and `shape.node[2]` provide the shape of the nodes associate to X - and Y -variables respectively. Current acceptable values are `"circle"` and `"rectangle"`. Defaults to `c("circle", "rectangle")`.

`lty.edge[1]` and `lty.egde[2]` give the line type to edges with positive and negative weight respectively. Can be one of `"solid"`, `"dashed"`, `"dotted"`, `"dotdash"`, `"longdash"` and `"twodash"`. Defaults to `c("solid", "solid")`.

`lwd.edge[1]` and `lwd.edge[2]` provide the line width to edges with positive and negative weight respectively. This attribute is of type double with a default of `c(1, 1)`.

Value

`network` return a list containing the following components:

<code>M</code>	the correlation matrix used by <code>network</code> .
<code>gR</code>	a graph object to save the graph for cytoscape use (requires to load the igraph package).

Warning

If the number of variables is high, the generation of the network generation can take some time.

nipals

Non-linear Iterative Partial Least Squares (NIPALS) algorithm

Description

This function performs NIPALS algorithm, i.e. the singular-value decomposition (SVD) of a data table that can contain missing values.

Usage

```
nipals(X, ncomp = 1, reconst = FALSE, max.iter = 500, tol = 1e-09)
```

Arguments

<code>X</code>	real matrix or data frame whose SVD decomposition is to be computed. It can contain missing values.
<code>ncomp</code>	integer, the number of components to keep. If missing <code>ncomp=ncol(X)</code> .
<code>reconst</code>	logical that specify if <code>nipals</code> must perform the reconstitution of the data using the <code>ncomp</code> components.
<code>max.iter</code>	integer, the maximum number of iterations.
<code>tol</code>	a positive real, the tolerance used in the iterative algorithm.

Details

The NIPALS algorithm (Non-linear Iterative Partial Least Squares) has been developed by H. Wold at first for PCA and later-on for PLS. It is the most commonly used method for calculating the principal components of a data set. It gives more numerically accurate results when compared with the SVD of the covariance matrix, but is slower to calculate.

This algorithm allows to realize SVD with missing data, without having to delete the rows with missing data or to estimate the missing data.

Value

The returned value is a list with components:

eig	vector containing the pseudosingular values of X, of length ncomp.
t	matrix whose columns contain the left singular vectors of X.
p	matrix whose columns contain the right singular vectors of X. Note that for a complete data matrix X, the return values eig, t and p such that $X = t * \text{diag}(\text{eig}) * t(p)$.
rec	matrix obtained by the reconstitution of the data using the ncomp components.

nutrimouse

Nutrimouse Dataset

Description

The nutrimouse dataset contains the expression measure of 120 genes potentially involved in nutritional problems and the concentrations of 21 hepatic fatty acids for forty mice.

Usage

```
data(nutrimouse)
```

Format

A list containing the following components:

gene data frame with 40 observations on 120 numerical variables.

lipid data frame with 40 observations on 21 numerical variables.

diet factor of 5 levels containing 40 labels for the diet factor.

genotype factor of 2 levels containing 40 labels for the diet factor.

Details

The data sets come from a nutrigenomic study in the mouse (Martin *et al.*, 2007) in which the effects of five regimens with contrasted fatty acid compositions on liver lipids and hepatic gene expression in mice were considered. Two sets of variables were acquired on forty mice:

- gene: expressions of 120 genes measured in liver cells, selected (among about 30,000) as potentially relevant in the context of the nutrition study. These expressions come from a nylon macroarray with radioactive labelling;
- lipid: concentrations (in percentages) of 21 hepatic fatty acids measured by gas chromatography.

Biological units (mice) were cross-classified according to two factors experimental design (4 replicates):

- Genotype: 2-levels factor, wild-type (WT) and PPAR α *-/-* (PPAR).
- Diet: 5-levels factor. Oils used for experimental diets preparation were corn and colza oils (50/50) for a reference diet (REF), hydrogenated coconut oil for a saturated fatty acid diet (COC), sunflower oil for an Omega6 fatty acid-rich diet (SUN), linseed oil for an Omega3-rich diet (LIN) and corn/colza/enriched fish oils for the FISH diet (43/43/14).

Value

none

Source

The nutrimouse dataset was provided by Pascal Martin from the Toxicology and Pharmacology Laboratory, National Institute for Agronomic Research, French.

pca

Principal Components Analysis

Description

Performs a principal components analysis on the given data matrix that can contain missing values. If data are complete 'pca' uses Singular Value Decomposition, if there are some missing values, it uses the NIPALS algorithm.

Usage

```
pca(X,
     ncomp = 2,
     center = TRUE,
     scale = FALSE,
     max.iter = 500,
     tol = 1e-09,
     logratio = 'none', # one of ('none', 'CLR', 'ILR')
     ilr.offset = 0.001,
     V = NULL,
     multilevel = NULL)
```

Arguments

X	a numeric matrix (or data frame) which provides the data for the principal components analysis. It can contain missing values.
ncomp	integer, if data is complete ncomp decides the number of components and associated eigenvalues to display from the pcasvd algorithm and if the data has missing values, ncomp gives the number of components to keep to perform the reconstitution of the data using the NIPALS algorithm. If NULL, function sets $ncomp = \min(nrow(X), ncol(X))$
center	a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of X can be supplied. The value is passed to scale .
scale	a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with prcomp function, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to scale .
max.iter	integer, the maximum number of iterations in the NIPALS algorithm.
tol	a positive real, the tolerance used in the NIPALS algorithm.
logratio	one of ('none', 'CLR', 'ILR'). Specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'

<code>ilr.offset</code>	When <code>logratio</code> is set to 'ILR', an offset must be input to avoid infinite value after the <code>logratio</code> transform, default to 0.001.
<code>V</code>	Matrix used in the <code>logratio</code> transformation if provided.
<code>multilevel</code>	sample information for multilevel decomposition for repeated measurements.

Details

The calculation is done either by a singular value decomposition of the (possibly centered and scaled) data matrix, if the data is complete or by using the NIPALS algorithm if there is data missing. Unlike `princomp`, the `print` method for these objects prints the results in a nice format and the `plot` method produces a bar plot of the percentage of variance explained by the principal components (PCs).

When using NIPALS (missing values), we make the assumption that the first ($\min(\text{ncol}(X), \text{nrow}(X))$) principal components will account for 100 % of the explained variance.

Note that `scale= TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.

Components are omitted if their standard deviations are less than or equal to `comp.tol` times the standard deviation of the first component. With the default null setting, no components are omitted. Other settings for `comp.tol` could be `comp.tol = sqrt(.Machine$double.eps)`, which would omit essentially constant components, or `comp.tol = 0`.

According to Filzmoser et al., a ILR log ratio transformation is more appropriate for PCA with compositional data. Both CLR and ILR are valid.

`Logratio` transform and multilevel analysis are performed sequentially as internal pre-processing step, through `logratio.transfo` and `withinVariation` respectively.

`Logratio` can only be applied if the data do not contain any 0 value (for count data, we thus advise the normalise raw data with a 1 offset). For ILR transformation and additional offset might be needed.

Value

`pca` returns a list with class "pca" and "prcomp" containing the following components:

<code>ncomp</code>	the number of principal components used.
<code>sdev</code>	the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix or by using NIPALS.
<code>rotation</code>	the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors).
<code>loadings</code>	same as 'rotation' to keep the mixOmics spirit
<code>x</code>	the value of the rotated data (the centred (and scaled if requested) data multiplied by the rotation/loadings matrix), also called the principal components.
<code>variates</code>	same as 'x' to keep the mixOmics spirit
<code>center, scale</code>	the centering and scaling used, or FALSE.
<code>explained_variance</code>	explained variance from the multivariate model, used for <code>plotIndiv</code>

 pcatune

Tune the number of principal components in PCA

Description

This function has been renamed [tune.pca](#).

Value

none

perf

Compute evaluation criteria for PLS, sPLS, PLS-DA, sPLS-DA, MINT and DIABLO

Description

Function to evaluate the performance of the fitted PLS, sparse PLS, PLS-DA, sparse PLS-DA, MINT (mint.splsda) and DIABLO (block.splsda) models using various criteria.

Usage

```
## S3 method for class 'mixo_pls'
perf(object, validation = c("Mfold", "loo"),
      folds = 10, progressBar = TRUE, ...)

## S3 method for class 'mixo_spls'
perf(object, validation = c("Mfold", "loo"),
      folds = 10, progressBar = TRUE, ...)

## S3 method for class 'mixo_plsda'
perf(object,
      dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
      validation = c("Mfold", "loo"),
      folds = 10, nrepeat = 1, auc = FALSE, progressBar = TRUE, cpus, ...)

## S3 method for class 'mixo_splsda'
perf(object,
      dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
      validation = c("Mfold", "loo"),
      folds = 10, nrepeat = 1, auc = FALSE, progressBar = TRUE, cpus, ...)

## S3 method for class 'mint.splsda'
perf(object,
      dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
      auc = FALSE, progressBar = TRUE, ...)

## S3 method for class 'sgccda'
```

```
perf(object,
      dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
      validation = c("Mfold", "loo"),
      folds = 10, nrepeat = 1, cpus, ...)
```

Arguments

object	object of class inherited from "pls", "plsda", "spls", "splda" or "mint.splsda". The function will retrieve some key parameters stored in that object.
dist	only applies to an object inheriting from "plsda", "splda" or "mint.splsda" to evaluate the classification performance of the model. Should be a subset of "max.dist", "centroids.dist", "mahalanobis.dist". Default is "all". See predict .
validation	character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (see below). Default is "Mfold".
folds	the folds in the Mfold cross-validation. See Details.
nrepeat	Number of times the Cross-Validation process is repeated. This is an important argument to ensure the estimation of the performance to be as accurate as possible.
auc	if TRUE calculate the Area Under the Curve (AUC) performance of the model.
progressBar	by default set to TRUE to output the progress bar of the computation.
cpus	Number of cpus to use when running the code in parallel.
...	not used

Details

Procedure. The process of evaluating the performance of a fitted model object is similar for all PLS-derived methods; a cross-validation approach is used to fit the method of object on folds-1 subsets of the data and then to predict on the subset left out. Different measures of performance are available depending on the model. Parameters such as logratio, multilevel, keepX or keepY are retrieved from object.

Parameters. If `validation = "Mfold"`, M-fold cross-validation is performed. `folds` specifies the number of folds to generate. The folds also can be supplied as a list of vectors containing the indexes defining each fold as produced by `split`. When using `validation = "Mfold"`, make sure that you repeat the process several times (as the results will be highly dependent on the random splits and the sample size).

If `validation = "loo"`, leave-one-out cross-validation is performed (in that case, there is no need to repeat the process).

Measures of performance. For fitted PLS and sPLS regression models, `perf` estimates the mean squared error of prediction (MSEP), R^2 , and Q^2 to assess the predictive perfity of the model using M-fold or leave-one-out cross-validation. Note that only the classic, regression and invariant modes can be applied. For sPLS, the MSEP, R^2 , and Q^2 criteria are averaged across all folds. Note that for PLS and sPLS objects, `perf` is performed on the pre-processed data after log ratio transform and multilevel analysis, if any.

Sparse methods. The sPLS, sPLS-DA and `sgccda` functions are run on several and different subsets of data (the cross-folds) and will certainly lead to different subset of selected features. Those are summarised in the output `features$stable` (see output Value below) to assess how often the variables are selected across all folds. Note that for PLS-DA and sPLS-DA objects, `perf` is performed

on the original data, i.e. before the pre-processing step of the log ratio transform and multilevel analysis, if any. In addition for these methods, the classification error rate is averaged across all folds.

The `mint.sPLS-DA` function estimates errors based on Leave-one-group-out cross validation (where each levels of `object$study` is left out (and predicted) once) and provides study-specific outputs (`study.specific.error`) as well as global outputs (`global.error`).

AUROC. For PLS-DA, sPLS-DA, mint.PLS-DA and mint.sPLS-DA methods: if `auc=TRUE`, Area Under the Curve (AUC) values are calculated from the predicted scores obtained from the `predict` function applied to the internal test sets in the cross-validation process, either for all samples or for study-specific samples (for mint models). Therefore we minimise the risk of overfitting. See [auroc](#) for more details. Our multivariate supervised methods already use a prediction threshold based on distances (see `predict`) that optimally determine class membership of the samples tested. As such AUC and ROC are not needed to estimate the performance of the model. We provide those outputs as complementary performance measures. See more details in our [mixOmics](#) article.

Prediction distances. See details from `?predict`, and also our supplemental material in the [mixOmics](#) article.

Repeats of the CV-folds. Repeated cross-validation implies that the whole CV process is repeated a number of times (`nrepeat`) to reduce variability across the different subset partitions. In the case of Leave-One-Out CV (`validation = 'loo'`), each sample is left out once (`folds = N` is set internally) and therefore `nrepeat` is by default 1.

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

More details about the PLS modes in `?pls`.

Value

For PLS and sPLS models, `perf` produces a list with the following components:

<code>MSEP</code>	Mean Square Error Prediction for each Y variable, only applies to object inherited from "pls", and "spls".
<code>R2</code>	a matrix of R^2 values of the Y -variables for models with $1, \dots, ncomp$ components, only applies to object inherited from "pls", and "spls".
<code>Q2</code>	if Y contains one variable, a vector of Q^2 values else a list with a matrix of Q^2 values for each Y -variable. Note that in the specific case of an sPLS model, it is better to have a look at the <code>Q2.total</code> criterion, only applies to object inherited from "pls", and "spls"
<code>Q2.total</code>	a vector of Q^2 -total values for models with $1, \dots, ncomp$ components, only applies to object inherited from "pls", and "spls"
<code>features</code>	a list of features selected across the folds (<code>\$stable.X</code> and <code>\$stable.Y</code>) for the <code>keepX</code> and <code>keepY</code> parameters from the input object.
<code>error.rate</code>	For PLS-DA and sPLS-DA models, <code>perf</code> produces a matrix of classification error rate estimation. The dimensions correspond to the components in the model and to the prediction method used, respectively. Note that error rates reported in any component include the performance of the model in earlier components for the specified <code>keepX</code> parameters (e.g. error rate reported for component 3 for <code>keepX = 20</code> already includes the fitted model on components 1 and 2 for <code>keepX = 20</code>). For more advanced usage of the <code>perf</code> function, see www.mixomics.org/methods/spls-da/ and consider using the <code>predict</code> function.

auc Averaged AUC values over the nrepeat

For mint.splsda models, perf produces the following outputs:

study.specific.error A list that gives BER, overall error rate and error rate per class, for each study

global.error A list that gives BER, overall error rate and error rate per class for all samples

predict A list of length ncomp that produces the predicted values of each sample for each class

class A list which gives the predicted class of each sample for each dist and each of the ncomp components. Directly obtained from the predict output.

auc AUC values

auc.study AUC values for each study

For sgccda models, perf produces the following outputs:

error.rate Prediction error rate for each block of object\$X and each dist

error.rate.per.class Prediction error rate for each block of object\$X, each dist and each class

predict Predicted values of each sample for each class, each block and each component

class Predicted class of each sample for each block, each dist, each component and each nrepeat

features a list of features selected across the folds (\$stable.X and \$stable.Y) for the keepX and keepY parameters from the input object.

AveragedPredict.class if more than one block, returns the average predicted class over the blocks (averaged of the Predict output and prediction using the max.dist distance)

AveragedPredict.error.rate if more than one block, returns the average predicted error rate over the blocks (using the AveragedPredict.class output)

WeightedPredict.class if more than one block, returns the weighted predicted class over the blocks (weighted average of the Predict output and prediction using the max.dist distance)

WeightedPredict.error.rate if more than one block, returns the weighted average predicted error rate over the blocks (using the WeightedPredict.class output)

MajorityVote if more than one block, returns the majority class over the blocks. NA for a sample means that there is no consensus on the predicted class for this particular sample over the blocks.

MajorityVote.error.rate if more than one block, returns the error rate of the MajorityVote output

WeightedVote if more than one block, returns the weighted majority class over the blocks. NA for a sample means that there is no consensus on the predicted class for this particular sample over the blocks.

WeightedVote.error.rate if more than one block, returns the error rate of the WeightedVote output

weights Returns the weights of each block used for the weighted predictions, for each nrepeat and each fold

`choice.ncomp` For supervised models; returns the optimal number of components for the model for each prediction distance using one-sided t-tests that test for a significant difference in the mean error rate (gain in prediction) when components are added to the model. See more details in Rohart et al 2017 Suppl. For more than one block, an optimal `ncomp` is returned for each prediction framework.

plot.perf

Plot for model performance

Description

Function to plot performance criteria, such as MSE_P, RMSE_P, R^2 , Q^2 for s/PLS methods, and classification performance for supervised methods, as a function of the number of components.

Usage

```

## S3 method for class 'perf.spls.mthd'
plot(x,
  criterion = "MSEP",

```

```

xlab = "number of components",
ylab = NULL,
LimQ2 = 0.0975,
LimQ2.col = "darkgrey",
cTicks = NULL,
layout = NULL,
...)

## S3 method for class 'perf.splsda.mthd'
plot(x,
dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
measure = c("all", "overall", "BER"),
col,
xlab = NULL,
ylab = NULL,
overlay=c("all", "measure", "dist"),
legend.position=c("vertical", "horizontal"),
sd = TRUE,
...)

## S3 method for class 'perf.mint.splsda.mthd'
plot(x,
dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
measure = c("all", "overall", "BER"),
col,
xlab = NULL,
ylab = NULL,
study = "global",
overlay= c("all", "measure", "dist"),
legend.position=c("vertical", "horizontal"),
...)

## S3 method for class 'perf.sgccda.mthd'
plot(x,
dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
measure = c("all", "overall", "BER"),
col,
weighted = TRUE,
xlab = NULL,
ylab = NULL,
overlay= c("all", "measure", "dist"),
legend.position=c("vertical", "horizontal"),
sd = TRUE,
...)

```

Arguments

x	an perf object.
criterion	character string. What type of validation criterion to plot for pls or spls. One of "MSEP", "RMSEP", "R2" or "Q2". See perf .
dist	prediction method applied in perf for plsda or splsda. See perf .

measure	Two misclassification measure are available: overall misclassification error overall or the Balanced Error Rate BER
col	character (or symbol) color to be used, possibly vector. One color per distance dist.
weighted	plot either the performance of the Majority vote or the Weighted vote.
study	Indicates which study-specific outputs to plot. A character vector containing some levels of object\$study, "all.partial" to plot all studies or "global" is expected. Default to "global".
overlay	parameter to overlay graphs; if 'all', only one graph is shown with all outputs; if 'measure', a graph is shown per distance; if 'dist', a graph is shown per measure.
legend.position	position of the legend, one of "vertical" (only one column) or "horizontal" (two columns).
xlab, ylab	titles for x and y axes. Typically character strings, but can be expressions (e.g., <code>expression(R^2)</code>).
LimQ2	numeric value. Signification limit for the components in the model. Default is <code>LimQ2 = 0.0975</code> .
LimQ2.col	character string specifying the color for the LimQ2 line to be plotted. If "none" the line will not be plotted.
cTicks	integer vector. Axis tickmark locations for the used number of components. Default is <code>1:ncomp</code> (see perf).
layout	numeric vector of length two giving the number of rows and columns in a multi panel display. If not specified, <code>plot.perf</code> tries to be intelligent.
sd	If 'nrepeat' was used in the call to 'perf', error bar shows the standard deviation if <code>sd=TRUE</code>
...	Further arguments sent to xyplot function.

Details

`plot.perf` creates one plot for each response variable in the model, laid out in a multi panel display. It uses [xyplot](#) for performing the actual plotting.

More details about the prediction distances in `?predict` and the supplemental material of the [mixOmics](#) article (Rohart et al. 2017).

breast.perf <- perf(res, nrepeat = 5)

plot(breast.perf)
plot(breast.perf, col=1:3)
plot(breast.perf, col=1:3, sd=FALSE)

## End(Not run)

```

plot.rcc

Canonical Correlations Plot

Description

This function provides scree plot of the canonical correlations.

Usage

```

## S3 method for class 'rcc'
plot(x, scree.type = c("pointplot", "barplot"), ...)

```

Arguments

x	object of class inheriting from "rcc".
scree.type	character string, (partially) matching one of "pointplot" or "barplot", determining the kind of scree plots to be produced.
...	arguments to be passed to other methods. For the "pointplot" type see points , for "barplot" type see barplot .

Value

none

Examples

```
data(nutrimouse)
X <- nutrimouse$lipid
Y <- nutrimouse$gene
nutri.res <- rcc(X, Y, lambda1 = 0.064, lambda2 = 0.008)

## 'pointplot' type scree
plot(nutri.res) #(default)

## Not run:
plot(nutri.res, pch = 19, cex = 1.2,
col = c(rep("red", 3), rep("darkblue", 18)))

## 'barplot' type scree
plot(nutri.res, scree.type = "barplot")

plot(nutri.res, scree.type = "barplot", density = 20, col = "black")

## End(Not run)
```

plot.tune

Plot for model performance

Description

Function to plot performance criteria, such as classification error rate or balanced error rate on a tune.splsda result.

Usage

```
## S3 method for class 'tune.splsda'
plot(x, optimal = TRUE, sd = TRUE, legend.position = "topright", col, ...)

## S3 method for class 'tune.block.splsda'
plot(x, sd = TRUE, col, ...)
```

Arguments

x	an <code>tune.splsda</code> object.
optimal	If TRUE, highlights the optimal keepX per component
sd	If 'nrepeat' was used in the call to 'tune.splsda', error bar shows the standard deviation if sd=TRUE
legend.position	position of the legend, one of "bottomright", "bottom", "bottomleft", "-left", "topleft", "top", "topright", "right" and "center".
col	character (or symbol) color to be used, possibly vector. One color per component.
...	Further arguments sent to <code>xyplot</code> function.

Details

`plot.tune.splsda` plots the classification error rate or the balanced error rate from `x$error.rate`, for each component of the model. A circle highlights the optimal number of variables oneach component.

`plot.tune.block.splsda` plots the classification error rate or the balanced error rate from `x$error.rate`, for each component of the model. The error rate is ordered by increasing value, the yaxis shows the optimal combination of keepX at the top (e.g. 'keepX on block 1'_'keepX on block 2'_'keepX on block 3')

Value

## End(Not run)

```

plotArrow

Arrow sample plot

Description

Represents samples from multiple coordinates.

Usage

```

plotArrow( object,
  comp = NULL,
  abline = FALSE,
  xlim = NULL,
  ylim = NULL,
  group=NULL,
  col,
  cex,
  pch,
  title=NULL,
  plot.arrows=TRUE,
  legend=FALSE,
  X.label = NULL,
  Y.label = NULL,
  ind.names=FALSE,
  position.names='centroid'
)

```

Arguments

object	object of class inheriting from mixOmics : PLS, sPLS, rCC, rGCCA, sGCCA, sGCCDA
comp	integer vector of length two indicating the components represented on the horizontal and the vertical axis to project the individuals.
abline	should the vertical and horizontal line through the center be plotted? Default set to FALSE
xlim	the ranges to be encompassed by the <i>x</i> axis, if NULL they are computed.
ylim	the ranges to be encompassed by the <i>y</i> axis, if NULL they are computed.
group	factor indicating the group membership for each sample. Coded as default for the supervised method sGCCDA, sPLSDA, but needs to be input for the unsupervised methods PLS, sPLS, rCC, rGCCA, sGCCA
col	character (or symbol) color to be used, color vector also possible.
cex	numeric character (or symbol) expansion, , color vector also possible.
pch	plot character. A character string or a vector of single characters or integers. See points for all alternatives.
title	set of characters for the title plot.
plot.arrows	boolean. Whether arrows should be added or not. Default is TRUE.
legend	boolean. Whether the legend should be added. Only for the supervised methods and if group!=NULL. Default is FALSE.
X.label	x axis titles.
Y.label	y axis titles.
ind.names	If TRUE, the row names of the first (or second) data matrix are used as sample names (see Details). Can be a vector of length the sample size to display sample names.
position.names	One of "centroid", "start", "end". Define where sample names are plotted when ind.names=TRUE. In a multiblock analysis, centroid and start will display similarly.

Details

Graphical of the samples (individuals) is displayed in a superimposed manner where each sample will be indicated using an arrow. The start of the arrow indicates the location of the sample in X in one plot, and the tip the location of the sample in Y in the other plot.

For objects of class "GCCA" and if there are more than 3 blocks, the start of the arrow indicates the centroid between all data sets for a given individual and the tips of the arrows the location of that individual in each block.

Short arrows indicate a strong agreement between the matching data sets, long arrows a disagreement between the matching data sets.

Value

plotDiablo

Graphical output for the DIABLO framework

Description

Function to visualise correlation between components from different data sets

Usage

```
plotDiablo(x, ncomp = 1, legend = TRUE, legend.ncol, ...)
```

Arguments

x	object of class inheriting from "block.splsda".
ncomp	Which component to plot calculated from each data set. Has to be lower than the minimum of object\$ncomp
legend	boolean. Whether the legend should be added. Default is TRUE.
legend.ncol	Number of columns for the legend. Default to min(5, nlevels(x\$Y))
...	not used

Details

The function uses a plot.data.frame to plot the component ncomp calculated from each data set to visualise whether DIABLO (block.splsda) is successful at maximising the correlation between each data sets' component. The lower triangular panel indicated the Pearson's correlation coefficient, the upper triangular panel the scatter plot.

Arguments

object	object of class inherited from any mixOmics : PLS, SPLS, PLS-DA, SPLS-DA, rCC, PCA, sPCA, I
comp	integer vector of length two (or three to 3d). The components that will be used on the horizontal and the vertical axis respectively to project the individuals.
rep.space	For objects inherited from "rcc", "pls", "spl", character string, (partially) matching one of "X-variate", "Y-variate" ,or "XY-variate", determining the subspace to project the individuals. Defaults to "X-variate" "pca" object and for "plsda" objects. For objects of class "pls" and "rcc", defaults, the tree subspaces represent the individuals. For objects of class "rgcca" and "sgcca", numerical value indicating the block data set form which to represent the individuals.

blocks	integer value of name of a block to be plotted using the GCCA module. See examples.
study	Indicates which study-specific outputs to plot. A character vector containing some levels of object\$study, "all.partial" to plot all studies or "global" is expected. Default to "global".
ind.names	either a character vector of names for the individuals to be plotted, or FALSE for no names. If TRUE, the row names of the first (or second) data matrix is used as names (see Details).
group	factor indicating the group membership for each sample, useful for ellipse plots. Coded as default for the supervised methods PLS-DA, SPLS-DA, sGCCDA, but needs to be input for the unsupervised methods PCA, sPCA, IPCA, sIPCA, PLS, sPLS, rCC, rGCCA, sGCCA.
col.per.group	character (or symbol) color to be used when 'group' is defined. Vector of the same length than the number of groups.
style	argument to be set to either 'graphics', 'lattice', 'ggplot2' or '3d' for a style of plotting. Default set to 'ggplot2'. See details. 3d is not available for MINT objects.
ellipse	boolean indicating if ellipse plots should be plotted. In the non supervised objects PCA, sPCA, IPCA, sIPCA, PLS, sPLS, rCC, rGCCA, sGCCA ellipse plot is only be plotted if the argument group is provided. In the PLS-DA, SPLS-DA, sGCCDA supervised object, by default the ellipse will be plotted according to the outcome Y.
ellipse.level	Numerical value indicating the confidence level of ellipse being plotted when ellipse =TRUE (i.e. the size of the ellipse). The default is set to 0.95, for a 95% region.
centroid	boolean indicating whether centroid points should be plotted. In the non supervised objects PCA, sPCA, IPCA, sIPCA, PLS, sPLS, rCC, rGCCA, sGCCA the centroid will only be plotted if the argument group is provided. The centroid will be calculated based on the group categories. In the supervised objects PLS-DA, SPLS-DA, sGCCDA the centroid will be calculated according to the outcome Y.
star	boolean indicating whether a star plot should be plotted, with arrows starting from the centroid (see argument centroid, and ending for each sample belonging to each group or outcome. In the non supervised objects PCA, sPCA, IPCA, sIPCA, PLS, sPLS, star plot is only be plotted if the argument group is provided. In the supervised objects PLS-DA, SPLS-DA, sGCCDA the star plot is plotted according to the outcome Y.
title	set of characters indicating the title plot.
subtitle	subtitle for each plot, only used when several block or study are plotted.
legend	boolean. Whether the legend should be added. Default is FALSE.
X.label	x axis titles.
Y.label	y axis titles.
Z.label	z axis titles (when style = '3d').
abline	should the vertical and horizontal line through the center be plotted? Default set to FALSE
xlim,ylim	numeric list of vectors of length 2 and length =length(blocks), giving the x and y coordinates ranges.
col	character (or symbol) color to be used, possibly vector.

<code>cex</code>	numeric character (or symbol) expansion, possibly vector.
<code>pch</code>	plot character. A character string or a vector of single characters or integers. See points for all alternatives.
<code>pch.levels</code>	Only used when <code>pch</code> is different from <code>col</code> or <code>col.per.group</code> , ie when <code>pch</code> creates a second factor. Only used for the legend.
<code>alpha</code>	Semi-transparent colors ($0 < \text{'alpha'} < 1$)
<code>axes.box</code>	for style '3d', argument to be set to either 'axes', 'box', 'bbox' or 'all', defining the shape of the box.
<code>layout</code>	layout parameter passed to <code>mfrow</code> . Only used when <code>study</code> is not "global"
<code>size.title</code>	size of the title
<code>size.subtitle</code>	size of the subtitle
<code>size.xlabel</code>	size of xlabel
<code>size.ylabel</code>	size of ylabel
<code>size.axis</code>	size of the axis
<code>size.legend</code>	size of the legend
<code>size.legend.title</code>	size of the legend title
<code>legend.title</code>	title of the legend
<code>legend.title.pch</code>	title of the second legend created by <code>pch</code> , if any.
<code>legend.position</code>	position of the legend, one of "bottom", "left", "top" and "right".
<code>point.lwd</code>	lwd of the points, used when <code>ind.names = FALSE</code>
<code>background</code>	color the background by the predicted class, see background.predict
<code>...</code>	external arguments or type <code>par</code> can be added with <code>style = 'graphics'</code>

Details

`plotIndiv` method makes scatter plot for individuals representation depending on the subspace of projection. Each point corresponds to an individual.

If `ind.names=TRUE` and row names is `NULL`, then `ind.names=1:n`, where `n` is the number of individuals. Also, if `pch` is an input, then `ind.names` is set to `FALSE` as we do not show both names and shapes.

`plotIndiv` can have a two layers legend. This is especially convenient when you have two grouping factors, such as a gender effect and a study effect, and you want to highlight both simulatenously on the graphical output. A first layer is coded by the group factor, the second by the `pch` argument. When `pch` is missing, a single layer legend is shown. If the group factor is missing, the `col` argument is used to create the grouping factor `group`. When a second grouping factor is needed and added via `pch`, `pch` needs to be a vector of length the number of samples. In the case where `pch` is a vector or length the number of groups, then we consider that the user wants a different `pch` for each level of group. This leads to a single layer legend and we merge `col` and `pch`. In the similar case where `pch` is a single value, then this value is used to represent all samples. See examples below for object of class `plsda` and `splsda`.

In the specific case of a single 'omics supervised model ([plsda](#), [splsda](#)), users can overlay prediction results to sample plots in order to visualise the prediction areas of each class, via the `background` input parameter. Note that this functionality is only available for models with less

than 2 components as the surfaces obtained for higher order components cannot be projected onto a 2D representation in a meaningful way. For more details, see [background.predict](#)

For customized plots (i.e. adding points, text), use the style = 'graphics' (default is ggplot2).

Note: the ellipse options were borrowed from the **ellipse**.

## End(Not run)

```

Description

This function provides a horizontal bar plot to visualise loading vectors. For discriminant analysis, it provides visualisation of highest or lowest mean/median value of the variables with color code corresponding to the outcome of interest.

Usage

```
## S3 method for class 'mixo_pls'
plotLoadings(object, block, comp = 1, col = NULL, ndisplay = NULL,
  size.name = 0.7, name.var = NULL, name.var.complete = FALSE, title = NULL, subtitle,
  size.title = rel(2), size.subtitle = rel(1.5), layout = NULL, border = NA,
  xlim = NULL, ... )

## S3 method for class 'mint_pls'
plotLoadings(object, study = "global", comp = 1, col = NULL, ndisplay = NULL,

  ndisplay = NULL, size.name = 0.7, size.legend = 0.8, name.var = NULL,
  name.var.complete = FALSE, title = NULL, subtitle, size.title = rel(1.8),
  size.subtitle = rel(1.4), legend = TRUE, legend.color = NULL,
  legend.title = 'Outcome', layout = NULL, border = NA, xlim = NULL, ... )
```

Arguments

object	object
contrib	a character set to 'max' or 'min' indicating if the color of the bar should correspond to the group with the maximal or minimal expression levels / abundance.
method	a character set to 'mean' or 'median' indicating the criterion to assess the contribution. We recommend using median in the case of count or skewed data.
study	Indicates which study are to be plotted. A character vector containing some levels of object\$study, "all.partial" to plot all studies or "global" is expected.
block	A single value indicating which block to consider in a sgccda object.
comp	integer value indicating the component of interest from the object.
col	color used in the barplot, only for object from non Discriminant analysis
plot	Boolean indicating of the plot should be output. If set to FALSE the user can extract the contribution matrix, see example. Default value is TRUE.

<code>show.ties</code>	Boolean. If TRUE then tie groups appear in the color set by <code>col.ties</code> , which will appear in the legend. Ties can happen when dealing with count data type. By default set to TRUE.
<code>col.ties</code>	Color corresponding to ties, only used if <code>show.ties=TRUE</code> and ties are present.
<code>ndisplay</code>	integer indicating how many of the most important variables are to be plotted (ranked by decreasing weights in each PLS-component). Useful to lighten a graph.
<code>size.name</code>	A numerical value giving the amount by which plotting the variable name text should be magnified or reduced relative to the default.
<code>size.legend</code>	A numerical value giving the amount by which plotting the legend text should be magnified or reduced relative to the default.
<code>name.var</code>	A character vector indicating the names of the variables. The names of the vector should match the names of the input data, see example.
<code>name.var.complete</code>	Boolean. If <code>name.var</code> is supplied with some empty names, <code>name.var.complete</code> allows you to use the initial variable names to complete the graph (from <code>colnames(X)</code>). Default to FALSE.
<code>title</code>	A set of characters to indicate the title of the plot. Default value is NULL.
<code>subtitle</code>	subtitle for each plot, only used when several block or study are plotted.
<code>size.title</code>	size of the title
<code>size.subtitle</code>	size of the subtitle
<code>legend</code>	Boolean indicating if the legend indicating the group outcomes should be added to the plot. Default value is TRUE.
<code>legend.color</code>	A color vector of length the number of group outcomes. See examples.
<code>legend.title</code>	A set of characters to indicate the title of the legend. Default value is NULL.
<code>layout</code>	Vector of two values (rows,cols) that indicates the layout of the plot. If layout is provided, the remaining empty subplots are still active
<code>border</code>	Argument from <code>barplot</code> : indicates whether to draw a border on the barplot.
<code>xlim</code>	Argument from <code>barplot</code> : limit of the x-axis. When plotting several block, a matrix is expected where each row is the <code>xlim</code> used for each of the blocks.
<code>...</code>	not used.

Details

The contribution of each variable for each component (depending on the object) is represented in a barplot where each bar length corresponds to the loading weight (importance) of the feature. The loading weight can be positive or negative.

For discriminant analysis, the color corresponds to the group in which the feature is most 'abundant'. Note that this type of graphical output is particularly insightful for count microbial data - in that latter case using the `method = 'median'` is advised. Note also that if the parameter `contrib` is not provided, plots are white.

For MINT analysis, `study="global"` plots the global loadings while partial loadings are plotted when `study` is a level of `object$study`. Since variable selection in MINT is performed at the global level, only the selected variables are plotted for the partial loadings even if the partial loadings are not sparse. See references. Importantly for multi plots, the legend accounts for one subplot in the layout design.

## End(Not run)

```

plotVar

Plot of Variables

Description

This function provides variables representation for (regularized) CCA, (sparse) PLS regression, PCA and (sparse) Regularized generalised CCA.

Usage

```
plotVar(object,
```

```

comp = NULL,
comp.select = comp,
plot=TRUE,
var.names = NULL,
blocks = NULL, # to choose which block data to plot, when using GCCA module
X.label = NULL,
Y.label = NULL,
Z.label = NULL,
abline = TRUE,
col,
cex,
pch,
font,
cutoff = 0,
rad.in = 0.5,
title="Correlation Circle Plots",
legend = FALSE,
legend.title = "Block",
style="ggplot2", # can choose between graphics,3d, lattice or ggplot2,
overlap = TRUE,
axes.box = "all",
label.axes.box = "both")

```

Arguments

object	object of class inheriting from "rcc", "pls", "plsda", "spl", "splda", "pca" or "spca".
comp	integer vector of length two. The components that will be used on the horizontal and the vertical axis respectively to project the variables. By default, comp=c(1,2) except when style='3d', comp=c(1:3)
comp.select	for the sparse versions, an input vector indicating the components on which the variables were selected. Only those selected variables are displayed. By default, comp.select=comp
plot	if TRUE (the default) then a plot is produced. If not, the summaries which the plots are based on are returned.
var.names	either a character vector of names for the variables to be plotted, or FALSE for no names. If TRUE, the col names of the first (or second) data matrix is used as names.
blocks	for an object of class "rgcca" or "sgcca", a numerical vector indicating the block variables to display.
X.label	x axis titles.
Y.label	y axis titles.
Z.label	z axis titles (when style = '3d').
abline	should the vertical and horizontal line through the center be plotted? Default set to FALSE
col	character or integer vector of colors for plotted character and symbols, can be of length 2 (one for each data set) or of length (p+q) (i.e. the total number of variables). See Details.

cex	numeric vector of character expansion sizes for the plotted character and symbols, can be of length 2 (one for each data set) or of length (p+q) (i.e. the total number of variables).
pch	plot character. A vector of single characters or integers, can be of length 2 (one for each data set) or of length (p+q) (i.e. the total number of variables). See points for all alternatives.
font	numeric vector of font to be used, can be of length 2 (one for each data set) or of length (p+q) (i.e. the total number of variables). See par for details.
cutoff	numeric between 0 and 1. Variables with correlations below this cutoff in absolute value are not plotted (see Details).
rad.in	numeric between 0 and 1, the radius of the inner circle. Defaults to 0.5.
title	character indicating the title plot.
legend	boolean when more than 3 blocks. Can be a character vector when one or 2 blocks to customize the legend. See examples. Default is FALSE.
legend.title	title of the legend
style	argument to be set to either 'graphics', 'lattice', 'ggplot2' or '3d' for a style of plotting.
overlap	boolean. Whether the variables should be plotted in one single figure. Default is TRUE.
axes.box	for style '3d', argument to be set to either 'axes', 'box', 'bbox' or 'all', defining the shape of the box.
label.axes.box	for style '3d', argument to be set to either 'axes', 'box', 'both', indicating which labels to print.

Details

plotVar produce a "correlation circle", i.e. the correlations between each variable and the selected components are plotted as scatter plot, with concentric circles of radius one et radius given by rad.in. Each point corresponds to a variable. For (regularized) CCA the components correspond to the equiangular vector between X - and Y -variates. For (sparse) PLS regression mode the components correspond to the X -variates. If mode is canonical, the components for X and Y variables correspond to the X - and Y -variates respectively.

For plsda and splsda objects, only the X variables are represented.

For spls and splsda objects, only the X and Y variables selected on dimensions comp are represented.

The arguments col, pch, cex and font can be either vectors of length two or a list with two vector components of length p and q respectively, where p is the number of X -variables and q is the number of Y -variables. In the first case, the first and second component of the vector determine the graphics attributes for the X - and Y -variables respectively. Otherwise, multiple arguments values can be specified so that each point (variable) can be given its own graphic attributes. In this case, the first component of the list correspond to the X attributs and the second component correspond to the Y attributs. Default values exist for this arguments.

Value

A list containing the following components:

x	a vector of coordinates of the variables on the x-axis.
y	a vector of coordinates of the variables on the y-axis.

Block the data block name each variable belongs to.
 names the name of each variable, matching their coordinates values.

## End(Not run)

```

pls

Partial Least Squares (PLS) Regression

Description

Function to perform Partial Least Squares (PLS) regression.

Usage

```

pls(X,
Y,
ncomp = 2,
scale = TRUE,
mode = c("regression", "canonical", "invariant", "classic"),
tol = 1e-06,

```

```

max.iter = 100,
near.zero.var = FALSE,
logratio="none",
multilevel=NULL,
all.outputs = TRUE)

```

Arguments

X	numeric matrix of predictors. NAs are allowed.
Y	numeric vector or matrix of responses (for multi-response models). NAs are allowed.
ncomp	the number of components to include in the model. Default to 2.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
logratio	one of ('none','CLR'). Default to 'none'
multilevel	Design matrix for repeated measurement analysis, where multilevel decomposition is required. For a one factor decomposition, the repeated measures on each individual, i.e. the individuals ID is input as the first column. For a 2 level factor decomposition then 2nd AND 3rd columns indicate those factors. See examples in ?spls).
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

pls function fit PLS models with 1, ... ,ncomp components. Multi-response models are fully supported. The X and Y datasets can contain missing values.

The type of algorithm to use is specified with the mode argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References). Different modes relate on how the Y matrix is deflated across the iterations of the algorithms - i.e. the different components.

- Regression mode: the Y matrix is deflated with respect to the information extracted/modelled from the local regression on X. Here the goal is to predict Y from X (Y and X play an asymmetric role). Consequently the latent variables computed to predict Y from X are different from those computed to predict X from Y.

- Canonical mode: the Y matrix is deflated to the information extracted/modelled from the local regression on Y. Here X and Y play a symmetric role and the goal is similar to a Canonical Correlation type of analysis.

- Invariant mode: the Y matrix is not deflated

- Classic mode: is similar to a regression mode. It gives identical results for the variates and loadings associated to the X data set, but differences for the loadings vectors associated to the Y data

set (different normalisations are used). Classic mode is the PLS2 model as defined by Tenenhaus (1998), Chap 9.

Note that in all cases the results are the same on the first component as deflation only starts after component 1.

The estimation of the missing values can be performed by the reconstitution of the data matrix using the `nipals` function. Otherwise, missing values are handled by casewise deletion in the `pls` function without having to delete the rows with missing data.

`logratio` transform and multilevel analysis are performed sequentially as internal pre-processing step, through `logratio.transfo` and `withinVariation` respectively.

Value

`pls` returns an object of class "pls", a list that contains the following components:

<code>X</code>	the centered and standardized original predictor matrix.
<code>Y</code>	the centered and standardized original response vector or matrix.
<code>ncomp</code>	the number of components included in the model.
<code>mode</code>	the algorithm used to fit the model.
<code>variates</code>	list containing the variates.
<code>loadings</code>	list containing the estimated loadings for the X and Y variates.
<code>names</code>	list containing the names to be used for individuals and variables.
<code>tol</code>	the tolerance used in the iterative algorithm, used for subsequent S3 methods
<code>iter</code>	Number of iterations of the algorithm for each component
<code>max.iter</code>	the maximum number of iterations, used for subsequent S3 methods
<code>nzv</code>	list containing the zero- or near-zero predictors information.
<code>scale</code>	whether scaling was applied per predictor.
<code>logratio</code>	whether log ratio transformation for relative proportion data was applied, and if so, which type of transformation.
<code>explained_variance</code>	amount of variance explained per component (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between data sets).
<code>input.X</code>	numeric matrix of predictors in X that was input, before any saling / <code>logratio</code> / multilevel transformation.
<code>mat.c</code>	matrix of coefficients from the regression of X / residual matrices X on the X -variates, to be used internally by <code>predict</code> .
<code>defl.matrix</code>	residual matrices X for each dimension.

## End(Not run)
```

plsda

Partial Least Squares Discriminant Analysis (PLS-DA).

Description

Function to perform standard Partial Least Squares regression to classify samples.

Usage

```
plsda(X,
      Y,
      ncomp = 2,
      scale = TRUE,
      mode = c("regression", "canonical", "invariant", "classic"),
      tol = 1e-06,
      max.iter = 100,
      near.zero.var = FALSE,
      logratio="none", # one of "none", "CLR"
      multilevel=NULL,
      all.outputs = TRUE)
```

Arguments

X	numeric matrix of predictors. NAs are allowed.
Y	a factor or a class vector for the discrete outcome.
ncomp	the number of components to include in the model. Default to 2.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
tol	Convergence stopping value.

<code>max.iter</code>	integer, the maximum number of iterations.
<code>near.zero.var</code>	boolean, see the internal <code>nearZeroVar</code> function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
<code>logratio</code>	one of ('none', 'CLR') specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'
<code>multilevel</code>	sample information for multilevel decomposition for repeated measurements. A numeric matrix or data frame indicating the repeated measures on each individual, i.e. the individuals ID. See examples in <code>?plsda</code> .
<code>all.outputs</code>	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

`plsda` function fit PLS models with 1, ..., `ncomp` components to the factor or class vector `Y`. The appropriate indicator matrix is created.

`logratio` transform and `multilevel` analysis are performed sequentially as internal pre-processing step, through `logratio.transfo` and `withinVariation` respectively.

`Logratio` can only be applied if the data do not contain any 0 value (for count data, we thus advise the normalise raw data with a 1 offset).

More details about the PLS modes in `?pls`.

Value

`plsda` returns an object of class "plsda", a list that contains the following components:

<code>X</code>	the centered and standardized original predictor matrix.
<code>Y</code>	the centered and standardized indicator response vector or matrix.
<code>ind.mat</code>	the indicator matrix.
<code>ncomp</code>	the number of components included in the model.
<code>variates</code>	list containing the <code>X</code> and <code>Y</code> variates.
<code>loadings</code>	list containing the estimated loadings for the variates.
<code>names</code>	list containing the names to be used for individuals and variables.
<code>nzv</code>	list containing the zero- or near-zero predictors information.
<code>tol</code>	the tolerance used in the iterative algorithm, used for subsequent S3 methods
<code>max.iter</code>	the maximum number of iterations, used for subsequent S3 methods
<code>iter</code>	Number of iterations of the algorithm for each component
<code>explained_variance</code>	amount of variance explained per component (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between <code>X</code> and the dummy matrix <code>Y</code>).
<code>mat.c</code>	matrix of coefficients from the regression of <code>X</code> / residual matrices <code>X</code> on the <code>X</code> -variates, to be used internally by <code>predict</code> .
<code>defl.matrix</code>	residual matrices <code>X</code> for each dimension.

## End(Not run)
```

predict

Predict Method for (mint).(block).(s)pls(da) methods

Description

Predicted values based on PLS models. New responses and variates are predicted using a fitted model and a new matrix of observations.

Usage

```
## S3 method for class 'mint.splsda'
predict(object, newdata, study.test,
  dist = c("all", "max.dist", "centroids.dist", "mahalanobis.dist"),
  multilevel, ...)
```

Arguments

<code>object</code>	object of class inheriting from " <code>(mint).(block).(s)pls(da)</code> ".
<code>newdata</code>	data matrix in which to look for explanatory variables to be used for prediction. Please note that this method does not perform multilevel decomposition or log ratio transformations, which need to be processed beforehand.
<code>study.test</code>	For MINT objects, grouping factor indicating which samples of newdata are from the same study. Overlap with <code>object\$study</code> are allowed.
<code>dist</code>	distance to be applied for discriminant methods to predict the class of new data, should be a subset of " <code>centroids.dist</code> ", " <code>mahalanobis.dist</code> " or " <code>max.dist</code> " (see Details). Defaults to " <code>all</code> ".
<code>multilevel</code>	Design matrix for multilevel analysis (for repeated measurements). A numeric matrix or data frame. For a one level factor decomposition, the input is a vector indicating the repeated measures on each individual, i.e. the individuals ID. For a two level decomposition with <code>splsda</code> models, the two factors are included in <code>Y</code> . Finally for a two level decomposition with <code>spls</code> models, 2nd AND 3rd columns in design indicate those factors (see example in <code>?splsda</code> and <code>?spls</code>).
<code>...</code>	not used currently.

Details

`predict` produces predicted values, obtained by evaluating the PLS-derived methods, returned by `(mint).(block).(s)pls(da)` in the frame `newdata`. Variates for `newdata` are also returned. Please note that this method performs multilevel decomposition and/or log ratio transformations if needed (`multilevel` is an input parameter while `logratio` is extracted from `object`).

Different prediction distances are proposed for discriminant analysis. The reason is that our supervised models work with a dummy indicator matrix of `Y` to indicate the class membership of each sample. The prediction of a new observation results in either a predicted dummy variable (output `object$predict`), or a predicted variate (output `object$variates`). Therefore, an appropriate distance needs to be applied to those predicted values to assign the predicted class. We propose distances such as 'maximum distance' for the predicted dummy variables, 'Mahalanobis distance' and 'Centroids distance' for the predicted variates.

"`max.dist`" is the simplest method to predict the class of a test sample. For each new individual, the class with the largest predicted dummy variable is the predicted class. This distance performs well in single data set analysis with multiclass problems (PLS-DA).

"`centroids.dist`" allocates to the new observation the class that mimimises the distance between the predicted score and the centroids of the classes calculated on the latent components or variates of the trained model.

"`mahalanobis.dist`" allocates the new sample the class defined as the centroid distance, but using the Mahalanobis metric in the calculation of the distance.

In practice we found that the centroid-based distances ("`centroids.dist`" and "`mahalanobis.dist`"), and specifically the Mahalanobis distance led to more accurate predictions than the maximum distance for complex classification problems and N-integration problems (`block.splsda`). The centroid

distances consider the prediction in dimensional space spanned by the predicted variates, while the maximum distance considers a single point estimate using the predicted scores on the last dimension of the model. The user can assess the different distances, and choose the prediction distance that leads to the best performance of the model, as highlighted from the tune and perf outputs

More (mathematical) details about the prediction distances are available in the supplemental of the mixOmics article (Rohart et al 2017).

For a visualisation of those prediction distances, see `background.predict` that overlays the prediction area in `plotIndiv` for a sPLS-DA object.

For MINT objects, the `study.test` argument is required and provides the grouping factor of `newdata`.

For multi block analysis (thus block objects), `newdata` is a list of matrices whose names are a subset of `names(object$X)` and missing blocks are allowed. Several predictions are returned, either for each block or for all blocks. For non discriminant analysis, the predicted values (`predict`) are returned for each block and these values are combined by average (`AveragedPredict`) or weighted average (`WeightedPredict`), using the weights of the blocks that are calculated as the correlation between a block's components and the outcome's components.

For discriminant analysis, the predicted class is returned for each block (`class`) and each distance (`dist`) and these predictions are combined by majority vote (`MajorityVote`) or weighted majority vote (`WeightedVote`), using the weights of the blocks that are calculated as the correlation between a block's components and the outcome's components. NA means that there is no consensus among the block. For PLS-DA and sPLS-DA objects, the prediction area can be visualised in `plotIndiv` via the `background.predict` function.

Value

`predict` produces a list with the following components:

<code>predict</code>	predicted response values. The dimensions correspond to the observations, the response variables and the model dimension, respectively. For a supervised model, it corresponds to the predicted dummy variables.
<code>variates</code>	matrix of predicted variates.
<code>B.hat</code>	matrix of regression coefficients (without the intercept).
<code>AveragedPredict</code>	if more than one block, returns the average predicted values over the blocks (using the <code>predict</code> output)
<code>WeightedPredict</code>	if more than one block, returns the weighted average of the predicted values over the blocks (using the <code>predict</code> and <code>weights</code> outputs)
<code>class</code>	predicted class of <code>newdata</code> for each 1, ..., <code>ncomp</code> components.
<code>MajorityVote</code>	if more than one block, returns the majority class over the blocks. NA for a sample means that there is no consensus on the predicted class for this particular sample over the blocks.
<code>WeightedVote</code>	if more than one block, returns the weighted majority class over the blocks. NA for a sample means that there is no consensus on the predicted class for this particular sample over the blocks.
<code>weights</code>	Returns the weights of each block used for the weighted predictions, for each <code>nrepeat</code> and each <code>fold</code>
<code>centroids</code>	matrix of coordinates for centroids.
<code>dist</code>	type of distance requested.
<code>vote</code>	majority vote result for multi block analysis (see details above).

print

Print Methods for CCA, (s)PLS, PCA and Summary objects

Description

Produce print methods for class "rcc", "pls", "spls", "pca", "rgcca", "sgcca" and "summary".

Usage

```
## S3 method for class 'rcc'
print(x, ...)

## S3 method for class 'mixo_pls'
print(x, ...)

## S3 method for class 'mixo_spls'
print(x, ...)

## S3 method for class 'pca'
print(x, ...)

## S3 method for class 'spca'
print(x, ...)

## S3 method for class 'rgcca'
print(x, ...)

## S3 method for class 'sgcca'
print(x, ...)

## S3 method for class 'summary'
print(x, ...)
```

Arguments

x	object of class inherited from "rcc", "pls", "spls", "pca", "spca", "rgcca", "sgcca" or "summary".
...	not used currently.

Details

print method for "rcc", "pls", "spls", "pca", "rgcca", "sgcca" class, returns a description of the x object including: the function used, the regularization parameters (if x of class "rcc"), the (s)PLS algorithm used (if x of class "pls" or "spls"), the samples size, the number of variables selected on each of the sPLS components (if x of class "spls") and the available components of the object.

print method for "summary" class, gives the (s)PLS algorithm used (if x of class "pls" or "spls"), the number of variates considered, the canonical correlations (if x of class "rcc"), the number of variables selected on each of the sPLS components (if x of class "spls") and the available components for Communalities Analysis, Redundancy Analysis and Variable Importance in the Projection (VIP).

Value

none

Examples

```
## print for objects of class 'rcc'
data(nutrimouse)
X <- nutrimouse$lipid
Y <- nutrimouse$gene
nutri.res <- rcc(X, Y, ncomp = 3, lambda1 = 0.064, lambda2 = 0.008)
print(nutri.res)

## Not run:
## print for objects of class 'summary'
more <- summary(nutri.res, cutoff = 0.65)
print(more)

## print for objects of class 'pls'
data(linnerud)
X <- linnerud$exercise
Y <- linnerud$physiological
linn.pls <- pls(X, Y)
print(linn.pls)

## print for objects of class 'spls'
data(liver.toxicity)
X <- liver.toxicity$gene
Y <- liver.toxicity$clinic
toxicity.spls <- spls(X, Y, ncomp = 3, keepX = c(50, 50, 50),
keepY = c(10, 10, 10))
print(toxicity.spls)

## End(Not run)
```

rcc

*Regularized Canonical Correlation Analysis***Description**

The function performs the regularized extension of the Canonical Correlation Analysis to seek correlations between two data matrices.

Usage

```
rcc(X,
    Y,
    ncomp = 2,
    method = "ridge", #choose between c("ridge", "shrinkage")
    lambda1 = 0,
    lambda2 = 0)
```

Arguments

<code>X</code>	numeric matrix or data frame ($n \times p$), the observations on the X variables. NAs are allowed.
<code>Y</code>	numeric matrix or data frame ($n \times q$), the observations on the Y variables. NAs are allowed.
<code>method</code>	One of "ridge" or "shrinkage". If "ridge", <code>lambda1</code> and <code>lambda2</code> need to be supplied (see also our function <code>tune.rcc</code>); if "shrinkage", parameters are directly estimated with Strimmer's formula, see below and reference.
<code>ncomp</code>	the number of components to include in the model. Default to 2.
<code>lambda1, lambda2</code>	a non-negative real. The regularization parameter for the X and Y data. Defaults to <code>lambda1=lambda2=0</code> . Only used if <code>method="ridge"</code>

Details

The main purpose of Canonical Correlations Analysis (CCA) is the exploration of sample correlations between two sets of variables X and Y observed on the same individuals (experimental units) whose roles in the analysis are strictly symmetric.

The `cancor` function performs the core of computations but additional tools are required to deal with data sets highly correlated (nearly collinear), data sets with more variables than units by example.

The `rcc` function, the regularized version of CCA, is one way to deal with this problem by including a regularization step in the computations of CCA. Such a regularization in this context was first proposed by Vinod (1976), then developed by Leurgans *et al.* (1993). It consists in the regularization of the empirical covariances matrices of X and Y by adding a multiple of the matrix identity, that is, $\text{Cov}(X) + \lambda_1 I$ and $\text{Cov}(Y) + \lambda_2 I$.

When `lambda1=0` and `lambda2=0`, `rcc` performs a classical CCA, if possible (i.e. when $n > p + q$).

The shrinkage estimates `method = "shrinkage"` can be used to bypass `tune.rcc` to choose the shrinkage parameters - which can be long and costly to compute with very large data sets. Note that both functions `tune.rcc` (which uses cross-validation) and the shrinkage parameters (which uses the formula from Schafer and Strimmer) may output different results.

Note: when method = "shrinkage" the input data are centered and scaled for the estimation of the shrinkage parameters and the calculation of the regularised variance-covariance matrices in `rcc`.

The estimation of the missing values can be performed by the reconstitution of the data matrix using the `nipals` function. Otherwise, missing values are handled by casewise deletion in the `rcc` function.

Value

`rcc` returns a object of class "rcc", a list that contains the following components:

<code>X</code>	the original X data.
<code>Y</code>	the original Y data.
<code>cor</code>	a vector containing the canonical correlations.
<code>lambda</code>	a vector containing the regularization parameters whether those were input if ridge method or directly estimated with the shrinkage method.
<code>loadings</code>	list containing the estimated coefficients used to calculate the canonical variates in X and Y .
<code>variates</code>	list containing the canonical variates.
<code>names</code>	list containing the names to be used for individuals and variables.

selectVar

Output of selected variables

Description

This function outputs the selected variables on each component for the sparse versions of the approaches (was also generalised to the non sparse versions for our internal functions).

Usage

```
## S3 method for class 'mixo_pls'
selectVar(object, comp = 1, block=NULL, ...)
## S3 method for class 'pca'
selectVar(object, comp = 1, block=NULL, ...)
## S3 method for class 'mixo_spls'
selectVar(object, comp = 1, block=NULL, ...)
## S3 method for class 'sgcca'
selectVar(object, comp = 1, block=NULL, ...)
## S3 method for class 'rgcca'
selectVar(object, comp = 1, block=NULL, ...)
```

Arguments

object	object of class inherited from "pls", "spls", "plsda", "splsda", "pca", "spca", "sipca".
comp	integer value indicating the component of interest.
block	for an object of class "sgcca", the block data sets can be specified as an input vector, for example c(1, 2) for the first two blocks. Default to NULL (all block data sets)
...	other arguments.

Details

selectVar provides the variables selected on a given component. \

name outputs the name of the selected variables (provided that the input data have colnames) ranked in decreasing order of importance.

value outputs the loading value for each selected variable, the loadings are ranked according to their absolute value.

These functions are only implemented for the sparse versions.

Value

none

sipca

Independent Principal Component Analysis

Description

Performs sparse independent principal component analysis on the given data matrix to enable variable selection.

Usage

```

sipca(X, ncomp, mode = c("deflation", "parallel"),
fun = c("logcosh", "exp"),
scale = FALSE, max.iter = 200,
tol = 1e-04, keepX = rep(50, ncomp),
w.init=NULL)

```

Arguments

X a numeric matrix (or data frame) which provides the data for the principal component analysis.

ncomp	integer, number of independent component to choose. Set by default to 3.
mode	character string. What type of algorithm to use when estimating the unmixing matrix, (partially) matching one of "deflation", "parallel". Default set to deflation.
fun	the function used in approximation to neg-entropy in the FastICA algorithm. Default set to logcosh, see details of FastICA.
scale	a logical value indicating whether rows of the data matrix X should be standardized beforehand.
max.iter	integer, maximum number of iterations to perform.
tol	a positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged, see fastICA package.
keepX	the number of variable to keep on each dimensions.
w.init	initial un-mixing matrix (unlike FastICA, this matrix is fixed here).

Details

See Details of ipca.

Soft thresholding is implemented on the independent loading vectors to obtain sparse loading vectors and enable variable selection.

Value

pca returns a list with class "ipca" containing the following components:

ncomp	the number of principal components used.
unmixing	the unmixing matrix of size (ncomp x ncomp)
mixing	the mixing matrix of size (ncomp x ncomp)
X	the centered data matrix
x	the principal components (with sparse independent loadings)
loadings	the sparse independent loading vectors
kurtosis	the kurtosis measure of the independent loading vectors

spca

Sparse Principal Components Analysis

Description

Performs a sparse principal components analysis to perform variable selection by using singular value decomposition.

Usage

```

spca(X, ncomp = 2, center = TRUE, scale = TRUE,
keepX = rep(ncol(X),ncomp), max.iter = 500,
tol = 1e-06, logratio = 'none', # one of ('none','CLR')
multilevel = NULL)

```

Arguments

X	a numeric matrix (or data frame) which provides the data for the sparse principal components analysis.
ncomp	integer, the number of components to keep.
center	a logical value indicating whether the variables should be shifted to be zero centered. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to scale .
scale	a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is TRUE. See details.
max.iter	integer, the maximum number of iterations to check convergence in each component.
tol	a positive real, the tolerance used in the iterative algorithm.

keepX	numeric vector of length ncomp, the number of variables to keep in loading vectors. By default all variables are kept in the model. See details.
logratio	one of ('none','CLR'). Specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'
multilevel	sample information for multilevel decomposition for repeated measurements.

Details

The calculation employs singular value decomposition of the (centered and scaled) data matrix and LASSO to generate sparsity on the loading vectors.

scale= TRUE is highly recommended as it will help obtaining orthogonal sparse loading vectors.

keepX is the number of variables to keep in loading vectors. The difference between number of columns of X and keepX is the degree of sparsity, which refers to the number of zeros in each loading vector.

Note that spca does not apply to the data matrix with missing values. The biplot function for spca is not available.

According to Filzmoser et al., a ILR log ratio transformation is more appropriate for PCA with compositional data. Both CLR and ILR are valid.

Logratio transform and multilevel analysis are performed sequentially as internal pre-processing step, through [logratio.transfo](#) and [withinVariation](#) respectively.

Logratio can only be applied if the data do not contain any 0 value (for count data, we thus advise the normalise raw data with a 1 offset). For ILR transformation and additional offset might be needed.

Value

spca returns a list with class "spca" containing the following components:

ncomp	the number of components to keep in the calculation.
varX	the adjusted cumulative percentage of variances explained.
keepX	the number of variables kept in each loading vector.
iter	the number of iterations needed to reach convergence for each component.
rotation	the matrix containing the sparse loading vectors.
x	the matrix containing the principal components.

## End(Not run)

```

spls

Sparse Partial Least Squares (sPLS)

Description

Function to perform sparse Partial Least Squares (sPLS). The sPLS approach combines both integration and variable selection simultaneously on two data sets in a one-step strategy.

Usage

```

spls(X,
Y,
ncomp = 2,
mode = c("regression", "canonical", "invariant", "classic"),
keepX,
keepY,
scale = TRUE,
tol = 1e-06,
max.iter = 100,
near.zero.var = FALSE,

```

```
logratio="none",
multilevel=NULL,
all.outputs = TRUE)
```

Arguments

<code>X</code>	numeric matrix of predictors. NAs are allowed.
<code>Y</code>	numeric vector or matrix of responses (for multi-response models). NAs are allowed. For multilevel analysis, a data frame of up to two columns is accepted.
<code>ncomp</code>	the number of components to include in the model (see Details). Default is set to from one to the rank of X .
<code>mode</code>	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
<code>keepX</code>	numeric vector of length <code>ncomp</code> , the number of variables to keep in X -loadings. By default all variables are kept in the model.
<code>keepY</code>	numeric vector of length <code>ncomp</code> , the number of variables to keep in Y -loadings. By default all variables are kept in the model.
<code>scale</code>	boolean. If <code>scale = TRUE</code> , each block is standardized to zero means and unit variances (default: <code>TRUE</code>)
<code>tol</code>	Convergence stopping value.
<code>max.iter</code>	integer, the maximum number of iterations.
<code>near.zero.var</code>	boolean, see the internal nearZeroVar function (should be set to <code>TRUE</code> in particular for data with many zero values). Setting this argument to <code>FALSE</code> (when appropriate) will speed up the computations. Default value is <code>FALSE</code>
<code>logratio</code>	one of ('none', 'CLR'). Default to 'none'
<code>multilevel</code>	Design matrix for repeated measurement analysis, where multilevel decomposition is required. For a one factor decomposition, the repeated measures on each individual, i.e. the individuals ID is input as the first column. For a 2 level factor decomposition then 2nd AND 3rd columns indicate those factors. See examples.
<code>all.outputs</code>	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = <code>TRUE</code> .

Details

`spls` function fit sPLS models with $1, \dots, ncomp$ components. Multi-response models are fully supported. The X and Y datasets can contain missing values.

The type of algorithm to use is specified with the `mode` argument. Four PLS algorithms are available: PLS regression ("regression"), PLS canonical analysis ("canonical"), redundancy analysis ("invariant") and the classical PLS algorithm ("classic") (see References and `?pls` for more details).

The estimation of the missing values can be performed by the reconstitution of the data matrix using the `nipals` function. Otherwise, missing values are handled by casewise deletion in the `spls` function without having to delete the rows with missing data.

`logratio` transform and multilevel analysis are performed sequentially as internal pre-processing step, through [logratio.transfo](#) and [withinVariation](#) respectively.

Multilevel sPLS enables the integration of data measured on two different data sets on the same individuals. This approach differs from multilevel sPLS-DA as the aim is to select subsets of variables from both data sets that are highly positively or negatively correlated across samples. The approach is unsupervised, i.e. no prior knowledge about the sample groups is included.

Value

spls returns an object of class "spls", a list that contains the following components:

X	the centered and standardized original predictor matrix.
Y	the centered and standardized original response vector or matrix.
ncomp	the number of components included in the model.
mode	the algorithm used to fit the model.
keepX	number of X variables kept in the model on each component.
keepY	number of Y variables kept in the model on each component.
variates	list containing the variates.
loadings	list containing the estimated loadings for the X and Y variates.
names	list containing the names to be used for individuals and variables.
tol	the tolerance used in the iterative algorithm, used for subsequent S3 methods
iter	Number of iterations of the algorithm for each component
max.iter	the maximum number of iterations, used for subsequent S3 methods
nzv	list containing the zero- or near-zero predictors information.
scale	whether scaling was applied per predictor.
logratio	whether log ratio transformation for relative proportion data was applied, and if so, which type of transformation.
explained_variance	amount of variance explained per component (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between data sets).
input.X	numeric matrix of predictors in X that was input, before any saling / logratio / multilevel transformation.
mat.c	matrix of coefficients from the regression of X / residual matrices X on the X-variates, to be used internally by predict.
defl.matrix	residual matrices X for each dimension.

## End(Not run)

```

splstda

Sparse Partial Least Squares Discriminant Analysis (sPLS-DA)

Description

Function to perform sparse Partial Least Squares to classify samples (supervised analysis) and select variables.

Usage

```

splstda(X,
Y,
ncomp = 2,
mode = c("regression", "canonical", "invariant", "classic"),
keepX,

```

```

scale = TRUE,
tol = 1e-06,
max.iter = 100,
near.zero.var = FALSE,
logratio="none", # one of "none", "CLR"
multilevel=NULL,
all.outputs = TRUE)

```

Arguments

X	numeric matrix of predictors. NAs are allowed.
Y	a factor or a class vector for the discrete outcome.
ncomp	the number of components to include in the model (see Details). Default is set to from one to the rank of X.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
keepX	numeric vector of length ncomp, the number of variables to keep in X-loadings. By default all variables are kept in the model.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
logratio	one of ('none', 'CLR') specifies the log ratio transformation to deal with compositional values that may arise from specific normalisation in sequencing data. Default to 'none'
multilevel	sample information for multilevel decomposition for repeated measurements. A numeric matrix or data frame indicating the repeated measures on each individual, i.e. the individuals ID. See examples.
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

splstda function fits an sPLS model with $1, \dots, ncomp$ components to the factor or class vector Y. The appropriate indicator (dummy) matrix is created. Logratio transform and multilevel analysis are performed sequentially as internal pre-processing step, through [logratio.transfo](#) and [withinVariation](#) respectively.

Logratio can only be applied if the data do not contain any 0 value (for count data, we thus advise the normalise raw data with a 1 offset).

More details about the PLS modes in ?pls.

Value

splstda returns an object of class "splstda", a list that contains the following components:

X	the centered and standardized original predictor matrix.
---	--

Y	the centered and standardized indicator response vector or matrix.
ind.mat	the indicator matrix.
ncomp	the number of components included in the model.
keepX	number of X variables kept in the model on each component.
variates	list containing the variates.
loadings	list containing the estimated loadings for the X and Y variates.
names	list containing the names to be used for individuals and variables.
nzv	list containing the zero- or near-zero predictors information.
tol	the tolerance used in the iterative algorithm, used for subsequent S3 methods
iter	Number of iterations of the algorithm for each component
max.iter	the maximum number of iterations, used for subsequent S3 methods
scale	boolean indicating whether the data were scaled in MINT S3 methods
logratio	whether logratio transformations were used for compositional data
explained_variance	amount of variance explained per component (note that contrary to PCA, this amount may not decrease as the aim of the method is not to maximise the variance, but the covariance between X and the dummy matrix Y).
mat.c	matrix of coefficients from the regression of X / residual matrices X on the X-variates, to be used internally by predict.
defl.matrix	residual matrices X for each dimension.

Examples

```

## First example
data(breast.tumors)
X <- breast.tumors$gene.exp
# Y will be transformed as a factor in the function,
# but we set it as a factor to set up the colors.
Y <- as.factor(breast.tumors$sample$treatment)

res <- splsda(X, Y, ncomp = 2, keepX = c(25, 25))

# individual names appear
plotIndiv(res, ind.names = Y, legend = TRUE, ellipse =TRUE)

## Not run:
## Second example: one-factor analysis with sPLS-DA, selecting a subset of variables
# as in the paper Liquet et al.
#-----
data(vac18)
X <- vac18$genes
Y <- vac18$stimulation
# sample indicates the repeated measurements
design <- data.frame(sample = vac18$sample)
Y = data.frame(stimul = vac18$stimulation)

# multilevel sPLS-DA model
res.1level <- splsda(X, Y = Y, ncomp = 3, multilevel = design,
keepX = c(30, 137, 123))

# set up colors for plotIndiv
col.stim <- c("darkblue", "purple", "green4","red3")
plotIndiv(res.1level, ind.names = Y, col.per.group = col.stim)

## Third example: two-factor analysis with sPLS-DA, selecting a subset of variables
# as in the paper Liquet et al.
#-----

data(vac18.simulated) # simulated data

X <- vac18.simulated$genes
design <- data.frame(sample = vac18.simulated$sample)
Y = data.frame( stimu = vac18.simulated$stimulation,
time = vac18.simulated$time)

res.2level <- splsda(X, Y = Y, ncomp = 2, multilevel = design,
keepX = c(200, 200))

plotIndiv(res.2level, group = Y$stimu, ind.names = vac18.simulated$time,
legend = TRUE, style = 'lattice')

## Fourth example: with more than two classes
# -----

data(liver.toxicity)

```

```

X <- as.matrix(liver.toxicity$gene)
# Y will be transformed as a factor in the function,
# but we set it as a factor to set up the colors.
Y <- as.factor(liver.toxicity$treatment[, 4])

splstda.liver <- splstda(X, Y, ncomp = 2, keepX = c(20, 20))

# individual name is set to the treatment
plotIndiv(splstda.liver, ind.names = Y, ellipse = TRUE, legend = TRUE)

## Fifth example: 16S data with multilevel decomposition and log ratio transformation
# -----

splstda.16S = splstda(
X = diverse.16S$data.TSS, # TSS normalised data
Y = diverse.16S$body-site,
multilevel = diverse.16S$sample, # multilevel decomposition
ncomp = 2,
keepX = c(10, 150),
logratio= 'CLR') # CLR log ratio transformation

plotIndiv(splstda.16S, ind.names = FALSE, pch = 16, ellipse = TRUE, legend = TRUE)
#OTUs selected at the family level
diverse.16S$taxonomy[selectVar(splstda.16S, comp = 1)$name, 'Family']

## End(Not run)

```

srbct

Small version of the small round blue cell tumors of childhood data

Description

This data set from Khan *et al.*, (2001) gives the expression measure of 2308 genes measured on 63 samples.

Usage

```
data(srbct)
```

Format

A list containing the following components:

`gene` data frame with 63 rows and 2308 columns. The expression measure of 2308 genes for the 63 subjects.

`class` A class vector containing the class tumour of each case (4 classes in total).

`gene.name` data frame with 2308 rows and 2 columns containing further information on the genes.

Value

none

Source

<http://research.nhgri.nih.gov/microarray/Supplement>

References

Khan et al. (2001). Classification and diagnostic prediction of cancers using gene expression profiling and artificial neural networks. *Nature Medicine* 7, Number 6, June.

stemcells

Human Stem Cells Data

Description

This data set contains the expression of a random subset of 400 genes in 125 samples from 4 independent studies and 3 cell types.

Usage

```
data(stemcells)
```

Format

A list containing the following components:

gene data matrix with 125 rows and 400 columns. Each row represents an experimental sample, and each column a single gene.

celltype a factor indicating the cell type of each sample.

study a factor indicating the study from which the sample was extracted.

Details

This data set contains the expression of a random subset of 400 genes in 125 samples from 4 independent studies and 3 cell types. Those studies can be combined and analysed using the MINT procedure.

Value

none

study_split	<i>divides a data matrix in a list of matrices defined by a factor</i>
-------------	--

Description

study_spli divides a data matrix in a list of matrices defined by a study input.

Usage

```
study_split(data, study)
```

Arguments

data	numeric matrix of predictors
study	grouping factor indicating which samples are from the same study

Value

study_split simply returns a list of the same length as the number of levels of study tha contains submatrices of data.

Author(s)

Florian Rohart

See Also

Examples

```
data(stemcells)
data = stemcells$gene
exp = stemcells$study

data.list = study_split(data, exp)

names(data.list)
lapply(data.list, dim)
table(exp)
```

Description

Produce summary methods for class "rcc", "pls" and "spls".

Usage

```
## S3 method for class 'rcc'
summary(object, what = c("all", "communalities", "redundancy"),
        cutoff = NULL, digits = 4, ...)

## S3 method for class 'mixo_pls'
summary(object, what = c("all", "communalities", "redundancy",
                        "VIP"), digits = 4, keep.var = FALSE, ...)

## S3 method for class 'mixo_spls'
summary(object, what = c("all", "communalities", "redundancy",
                        "VIP"), digits = 4, keep.var = FALSE, ...)
```

Arguments

object	object of class inherited from "rcc", "pls" or "spls".
cutoff	real between 0 and 1. Variables with all correlations components below this cutoff in absolute value are not showed (see Details).
digits	integer, the number of significant digits to use when printing. Defaults to 4.
what	character string or vector. Should be a subset of c("all", "summarised", "communalities", "redundancy", "VIP"). "VIP" is only available for (s)PLS. See Details.
keep.var	boolean. If TRUE only the variables with loadings not zero (as selected by spls) are showed. Defaults to FALSE.
...	not used currently.

Details

The information in the rcc, pls or spls object is summarised, it includes: the dimensions of X and Y data, the number of variates considered, the canonical correlations (if object of class "rcc") and the (s)PLS algorithm used (if object of class "pls" or "spls") and the number of variables selected on each of the sPLS components (if x of class "spls").

"communalities" in what gives Communalities Analysis. "redundancy" display Redundancy Analysis. "VIP" gives the Variable Importance in the Projection (VIP) coefficients fit by pls or spls. If what is "all", all are given.

For class "rcc", when a value to cutoff is specified, the correlations between each variable and the equiangular vector between X- and Y-variates are computed. Variables with at least one correlation componente bigger than cutoff are showed. The defaults is cutoff=NULL all the variables are given.

Value

The function `summary` returns a list with components:

<code>ncomp</code>	the number of components in the model.
<code>cor</code>	the canonical correlations.
<code>cutoff</code>	the cutoff used.
<code>keep.var</code>	list containing the name of the variables selected.
<code>mode</code>	the algorithm used in <code>pls</code> or <code>spls</code> .
<code>Cm</code>	list containing the communalities.
<code>Rd</code>	list containing the redundancy.
<code>VIP</code>	matrix of VIP coefficients.
<code>what</code>	subset of <code>c("all", "communalities", "redundancy", "VIP")</code> .
<code>digits</code>	the number of significant digits to use when printing.
<code>method</code>	method used: <code>rcc</code> , <code>pls</code> or <code>spls</code> .

Author(s)

Sébastien Déjean, Ignacio González and Kim-Anh Lê Cao.

tune	<i>Generic function to choose the parameters in the different methods in mixOmics</i>
------	---

Description

Wrapper of all tuning functions.

Usage

```
tune(method,
      X,
      Y,
      multilevel,
      ncomp,
      study, # mint.splsda
      test.keepX = c(5, 10, 15), # all but pca, rcc
      test.keepY = NULL, # rcc, multilevel
      already.tested.X, # all but pca, rcc
      already.tested.Y, #multilevel
      mode = "regression", # multilevel
      nrepeat = 1, #multilevel, splsda
      grid1 = seq(0.001, 1, length = 5), # rcc
      grid2 = seq(0.001, 1, length = 5), # rcc
      validation = "Mfold", # all but pca
      folds = 10, # all but pca
      dist = "max.dist", # all but pca, rcc
      measure = c("BER"), # all but pca, rcc
      auc = FALSE,
      progressBar = TRUE, # all but pca, rcc
      near.zero.var = FALSE, # all but pca, rcc
      logratio = "none", # all but pca, rcc
      center = TRUE, # pca
      scale = TRUE, # mint, splsda
      max.iter = 100, #pca
      tol = 1e-09,
      light.output = TRUE # mint, splsda
    )
```

Arguments

method	This parameter is used to pass all other argument to the suitable function. method has to be one of the following: "spls", "splsda", "mint.splsda", "rcc", "pca".
X	numeric matrix of predictors. NAs are allowed.
Y	Either a factor or a class vector for the discrete outcome, or a numeric vector or matrix of continuous responses (for multi-response models).
multilevel	Design matrix for multilevel analysis (for repeated measurements) that indicates the repeated measures on each individual, i.e. the individuals ID. See Details.
ncomp	the number of components to include in the model.

study	grouping factor indicating which samples are from the same study
test.keepX	numeric vector for the different number of variables to test from the X data set
test.keepY	If method = 'spls', numeric vector for the different number of variables to test from the Y data set
already.tested.X	Optional, if ncomp > 1 A numeric vector indicating the number of variables to select from the X data set on the firsts components.
already.tested.Y	if method = 'spls' and if(ncomp > 1) numeric vector indicating the number of variables to select from the Y data set on the first components
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
nrepeat	Number of times the Cross-Validation process is repeated.
grid1, grid2	vector numeric defining the values of lambda1 and lambda2 at which cross-validation score should be computed. Defaults to grid1=grid2=seq(0.001, 1, length=5).
validation	character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (see below). Default is "Mfold".
folds	the folds in the Mfold cross-validation. See Details.
dist	distance metric to use for splsda to estimate the classification error rate, should be a subset of "centroids.dist", "mahalanobis.dist" or "max.dist" (see Details).
measure	Two misclassification measure are available: overall misclassification error overall or the Balanced Error Rate BER
auc	if TRUE calculate the Area Under the Curve (AUC) performance of the model.
progressBar	by default set to TRUE to output the progress bar of the computation.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default value is FALSE
logratio	one of ('none','CLR'). Default to 'none'
center	a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of X can be supplied. The value is passed to scale .
scale	a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with prcomp function, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to scale .
max.iter	integer, the maximum number of iterations for the NIPALS algorithm.
tol	a positive real, the tolerance used for the NIPALS algorithm.
light.output	if set to FALSE, the prediction/classification of each sample for each of test.keepX and each comp is returned.

Details

The tune function called the function predict. more details about most arguments are detailed in [?predict](#).

Also see the help file corresponding to your method, e.g. [tune.splsda](#). Note that only the arguments used in the tune function corresponding to method are passed on.

Some details on the use of the `nrepeat` argument are provided in `?perf`.

More details about the prediction distances in `?predict` and the supplemental material of the `mixOmics` article (Rohart et al. 2017). More details about the PLS modes are in `?pls`.

Value

Depending on the type of analysis performed and the input arguments, a list that may contain:

<code>error.rate</code>	returns the prediction error for each <code>test.keepX</code> on each component, averaged across all repeats and subsampling folds. Standard deviation is also output. All error rates are also available as a list.
<code>choice.keepX</code>	returns the number of variables selected (optimal <code>keepX</code>) on each component.
<code>choice.ncomp</code>	For supervised models; returns the optimal number of components for the model for each prediction distance using one-sided t-tests that test for a significant difference in the mean error rate (gain in prediction) when components are added to the model. See more details in Rohart et al 2017 Suppl. For more than one block, an optimal <code>ncomp</code> is returned for each prediction framework.
<code>error.rate.class</code>	returns the error rate for each level of <code>Y</code> and for each component computed with the optimal <code>keepX</code>
<code>predict</code>	Prediction values for each sample, each <code>test.keepX</code> , each comp and each repeat. Only if <code>light.output=FALSE</code>
<code>class</code>	Predicted class for each sample, each <code>test.keepX</code> , each comp and each repeat. Only if <code>light.output=FALSE</code>
<code>auc</code>	AUC mean and standard deviation if the number of categories in <code>Y</code> is greater than 2, see details above. Only if <code>auc = TRUE</code>
<code>cor.value</code>	only if multilevel analysis with 2 factors: correlation between latent variables.

tune.block.splsda

Tuning function for block.splsda method (N-integration with sparse Discriminant Analysis)

Description

Computes M-fold or Leave-One-Out Cross-Validation scores based on a user-input grid to determine the optimal parsy parameters values for method `block.splsda`.

Usage

```
tune.block.splsda(X, Y,
  indY,
  ncomp = 2,
  test.keepX,
  already.tested.X,
  validation = "Mfold",
  folds = 10,
  dist = "max.dist",
  measure = "BER",
  weighted = TRUE,
  progressBar = TRUE,
  tol = 1e-06,
  max.iter = 100,
  near.zero.var = FALSE,
  nrepeat = 1,
  design,
  scheme= "horst",
  scale = TRUE,
  init = "svd",
  light.output = TRUE,
  cpus,
  name.save=NULL
)
```

Arguments

<code>X</code>	numeric matrix of predictors. NAs are allowed.
<code>Y</code>	<code>if(method = 'spls')</code> numeric vector or matrix of continuous responses (for multi-response models) NAs are allowed.
<code>indY</code>	To be supplied if <code>Y</code> is missing, indicates the position of the matrix / vector response in the list <code>X</code>
<code>ncomp</code>	the number of components to include in the model.
<code>test.keepX</code>	A list of length the number of blocks in <code>X</code> (without the outcome). Each entry of this list is a numeric vector for the different <code>keepX</code> values to test for that specific block.
<code>already.tested.X</code>	Optional, if <code>ncomp > 1</code> A numeric vector indicating the number of variables to select from the <code>X</code> data set on the firsts components.
<code>validation</code>	character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (see below). Default is "Mfold".
<code>folds</code>	the folds in the Mfold cross-validation. See Details.
<code>dist</code>	distance metric to use for <code>splsda</code> to estimate the classification error rate, should be a subset of "centroids.dist", "mahalanobis.dist" or "max.dist" (see Details).

measure	Two misclassification measure are available: overall misclassification error overall or the Balanced Error Rate BER
weighted	tune using either the performance of the Majority vote or the Weighted vote.
progressBar	by default set to TRUE to output the progress bar of the computation.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal <code>nearZeroVar</code> function (should be set to TRUE in particular for data with many zero values). Default value is FALSE
nrepeat	Number of times the Cross-Validation process is repeated.
design	numeric matrix of size (number of blocks in X) x (number of blocks in X) with 0 or 1 values. A value of 1 (0) indicates a relationship (no relationship) between the blocks to be modelled. If Y is provided instead of <code>indY</code> , the design matrix is changed to include relationships to Y.
scheme	Either "horst", "factorial" or "centroid". Default = centroid, see reference.
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances. Default = TRUE.
init	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default = svd.
light.output	if set to FALSE, the prediction/classification of each sample for each of <code>test.keepX</code> and each comp is returned.
cpus	Number of cpus to use when running the code in parallel.
name.save	character string for the name of the file to be saved.

Details

This tuning function should be used to tune the `keepX` parameters in the `block.splsda` function (N-integration with sparse Discriminant Analysis).

M-fold or LOO cross-validation is performed with stratified subsampling where all classes are represented in each fold.

If `validation = "Mfold"`, M-fold cross-validation is performed. The number of folds to generate is to be specified in the argument `fold`.

If `validation = "loo"`, leave-one-out cross-validation is performed. By default `fold` is set to the number of unique individuals.

All combination of `test.keepX` values are tested. A message informs how many will be fitted on each component for a given `test.keepX`.

More details about the prediction distances in `?predict` and the supplemental material of the `mixOmics` article (Rohart et al. 2017). Details about the PLS modes are in `?pls`.

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

Value

A list that contains:

error.rate	returns the prediction error for each test.keepX on each component, averaged across all repeats and subsampling folds. Standard deviation is also output. All error rates are also available as a list.
choice.keepX	returns the number of variables selected (optimal keepX) on each component, for each block.
choice.ncomp	returns the optimal number of components for the model fitted with \$choice.keepX.
error.rate.class	returns the error rate for each level of Y and for each component computed with the optimal keepX
predict	Prediction values for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE
class	Predicted class for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE
cor.value	compute the correlation between latent variables for two-factor sPLS-DA analysis.

tune.mint.splsda

Estimate the parameters of mint.splsda method

Description

Computes Leave-One-Group-Out-Cross-Validation (LOGOCV) scores on a user-input grid to determine optimal values for the sparsity parameters in `mint.splsda`.

Usage

```

tune.mint.splsda(X, Y, ncomp = 1, study, test.keepX = c(5, 10, 15), already.tested.X,
dist = "max.dist", measure = "BER", auc = FALSE, progressBar = TRUE,
scale = TRUE, tol = 1e-06, max.iter = 100, near.zero.var = FALSE, light.output = TRUE )

```

Arguments

X	numeric matrix of predictors. NAs are allowed.
Y	Outcome. Numeric vector or matrix of responses (for multi-response models)
ncomp	Number of components to include in the model (see Details). Default to 1
study	grouping factor indicating which samples are from the same study
test.keepX	numeric vector for the different number of variables to test from the <i>X</i> data set

<code>already.tested.X</code>	if <code>ncomp > 1</code> Numeric vector indicating the number of variables to select from the <code>X</code> data set on the firsts components
<code>dist</code>	only applies to an object inheriting from "plsda" or "splsda" to evaluate the classification performance of the model. Should be a subset of "max.dist", "centroids.dist", "mahalanobis.dist". Default is "all". See predict .
<code>measure</code>	Two misclassification measure are available: overall misclassification error <code>overall</code> or the Balanced Error Rate <code>BER</code>
<code>auc</code>	if TRUE calculate the Area Under the Curve (AUC) performance of the model.
<code>progressBar</code>	by default set to TRUE to output the progress bar of the computation.
<code>scale</code>	boolean. If <code>scale = TRUE</code> , each block is standardized to zero means and unit variances (default: TRUE)
<code>tol</code>	Convergence stopping value.
<code>max.iter</code>	integer, the maximum number of iterations.
<code>near.zero.var</code>	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default value is FALSE
<code>light.output</code>	if set to FALSE, the prediction/classification of each sample for each of <code>test.keepX</code> and each comp is returned.

Details

This function performs a Leave-One-Group-Out-Cross-Validation (LOGOCV), where each of `study` is left out once. It returns a list of variables of `X` that were selected on each of the `ncomp` components. Then, a [mint.splsda](#) can be performed with `keepX` set as the output choice `keepX`.

All component 1 : `ncomp` are tuned, except the first ones for which a `already.tested.X` is provided. See examples below.

The function outputs the optimal number of components that achieve the best performance based on the overall error rate or BER. The assessment is data-driven and similar to the process detailed in (Rohart et al., 2016), where one-sided t-tests assess whether there is a gain in performance when adding a component to the model. Our experience has shown that in most case, the optimal number of components is the number of categories in `Y - 1`, but it is worth tuning a few extra components to check (see our website and case studies for more details).

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

More details about the prediction distances in `?predict` and the supplemental material of the [mixOmics](#) article (Rohart et al. 2017).

Value

The returned value is a list with components:

<code>error.rate</code>	returns the prediction error for each <code>test.keepX</code> on each component, averaged across all repeats and subsampling folds. Standard deviation is also output. All error rates are also available as a list.
<code>choice.keepX</code>	returns the number of variables selected (optimal <code>keepX</code>) on each component.
<code>choice.ncomp</code>	returns the optimal number of components for the model fitted with <code>\$choice.keepX</code>

```

error.rate.class      returns the error rate for each level of Y and for each component computed with
                      the optimal keepX
predict              Prediction values for each sample, each test.keepX and each comp.
class               Predicted class for each sample, each test.keepX and each comp.

```

## End(Not run)

```

tune.pca

*Tune the number of principal components in PCA***Description**

tune.pca can be used to quickly visualise the proportion of explained variance for a large number of principal components in PCA.

Usage

```
tune.pca(X, ncomp = NULL, center = TRUE, scale = FALSE,
max.iter = 500, tol = 1e-09, logratio = 'none',
V = NULL, multilevel = NULL)
```

Arguments

X	a numeric matrix (or data frame) which provides the data for the principal components analysis. It can contain missing values.
ncomp	integer, the number of components to initially analyse in tune.pca to choose a final ncomp for pca. If NULL, function sets ncomp = min(nrow(X), ncol(X))
center	a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of X can be supplied. The value is passed to scale .
scale	a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with prcomp function, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of X can be supplied. The value is passed to scale .
max.iter	integer, the maximum number of iterations for the NIPALS algorithm.
tol	a positive real, the tolerance used for the NIPALS algorithm.
logratio	one of ('none', 'CLR', 'ILR'). Default to 'none'
V	Matrix used in the logratio transformation id provided.
multilevel	Design matrix for multilevel analysis (for repeated measurements).

Details

The calculation is done either by a singular value decomposition of the (possibly centered and scaled) data matrix, if the data is complete or by using the NIPALS algorithm if there is data missing. Unlike [princomp](#), the print method for these objects prints the results in a nice format and the plot method produces a bar plot of the percentage of variance explained by the principal components (PCs).

When using NIPALS (missing values), we make the assumption that the first (min(ncol(X), nrow(X)) principal components will account for 100 % of the explained variance.

Note that scale= TRUE cannot be used if there are zero or constant (for center = TRUE) variables.

Components are omitted if their standard deviations are less than or equal to comp.tol times the standard deviation of the first component. With the default null setting, no components are omitted. Other settings for comp.tol could be comp.tol = sqrt(.Machine\$double.eps), which would omit essentially constant components, or comp.tol = 0.

logratio transform and multilevel analysis are performed sequentially as internal pre-processing step, through `logratio.transfo` and `withinVariation` respectively.

Value

`tune.pca` returns a list with class `"tune.pca"` containing the following components:

<code>sdev</code>	the square root of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).
<code>explained_variance</code>	the proportion of explained variance accounted for by each principal component is calculated using the eigenvalues
<code>cum.var</code>	the cumulative proportion of explained variance accounted for by the sequential accumulation of principal components is calculated using the sum of the proportion of explained variance

Examples

```
data(liver.toxicity)
tune <- tune.pca(liver.toxicity$gene, center = TRUE, scale = TRUE)
tune
```

tune.rcc

Estimate the parameters of regularization for Regularized CCA

Description

Computes leave-one-out or M-fold cross-validation scores on a two-dimensional grid to determine optimal values for the parameters of regularization in `rcc`.

Usage

```
tune.rcc(X, Y, grid1 = seq(0.001, 1, length = 5),
grid2 = seq(0.001, 1, length = 5),
validation = c("loo", "Mfold"),
folds = 10, plot = TRUE)
```

Arguments

<code>X</code>	numeric matrix or data frame ($n \times p$), the observations on the X variables. NAs are allowed.
<code>Y</code>	numeric matrix or data frame ($n \times q$), the observations on the Y variables. NAs are allowed.
<code>grid1, grid2</code>	vector numeric defining the values of <code>lambda1</code> and <code>lambda2</code> at which cross-validation score should be computed. Defaults to <code>grid1=grid2=seq(0.001, 1, length=5)</code> .
<code>validation</code>	character string. What kind of (internal) cross-validation method to use, (partially) matching one of "loo" (leave-one-out) or "Mfolds" (M-folds). See Details.
<code> folds</code>	positive integer. Number of folds to use if <code>validation="Mfold"</code> . Defaults to <code> folds=10</code> .
<code> plot</code>	logical argument indicating whether a image map should be plotted by calling the <code>imgCV</code> function.

Details

If `validation="Mfolds"`, M-fold cross-validation is performed by calling `Mfold`. When `folds` is given, the elements of `folds` should be integer vectors specifying the indices of the validation sample and the argument `M` is ignored. Otherwise, the folds are generated. The number of cross-validation folds is specified with the argument `M`.

If `validation="loo"`, leave-one-out cross-validation is performed by calling the `loo` function. In this case the arguments `folds` and `M` are ignored.

The estimation of the missing values can be performed by the reconstitution of the data matrix using the `nipals` function. Otherwise, missing values are handled by casewise deletion in the `rcc` function.

Value

The returned value is a list with components:

<code>opt.lambda1,</code>	
<code>opt.lambda2</code>	value of the parameters of regularization on which the cross-validation method reached it optimal.
<code>opt.score</code>	the optimal cross-validation score reached on the grid.
<code>grid1, grid2</code>	original vectors <code>grid1</code> and <code>grid2</code> .
<code>mat</code>	matrix containing the cross-validation score computed on the grid.

```

tune.spls

*Tuning functions for sPLS method***Description**

Computes M-fold or Leave-One-Out Cross-Validation scores on a user-input grid to determine optimal values for the sparsity parameters in spls.

Usage

```

tune.spls(X, Y, ncomp = 1,
test.keepX = c(5, 10, 15), already.tested.X,
validation = "Mfold", folds = 10, measure = "MSE", scale = TRUE,
progressBar = TRUE, tol = 1e-06, max.iter = 100, near.zero.var = FALSE,
nrepeat = 1, multilevel = NULL, light.output = TRUE, cpus)

```

Arguments

X	numeric matrix of predictors. NAs are allowed.
Y	if(method = 'spls') numeric vector or matrix of continuous responses (for multi-response models) NAs are allowed.
ncomp	the number of components to include in the model.
test.keepX	numeric vector for the different number of variables to test from the X data set
already.tested.X	Optional, if ncomp > 1 A numeric vector indicating the number of variables to select from the X data set on the firsts components.
validation	character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (see below). Default is "Mfold".
folds	the folds in the Mfold cross-validation. See Details.
measure	One of MSE, MAE, Bias or R2. Default to MSE. See details
scale	boolean. If scale = TRUE, each block is standardized to zero means and unit variances (default: TRUE)
progressBar	by default set to TRUE to output the progress bar of the computation.
tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Default value is FALSE

nrepeat	Number of times the Cross-Validation process is repeated.
multilevel	Design matrix for multilevel analysis (for repeated measurements) that indicates the repeated measures on each individual, i.e. the individuals ID. See Details.
light.output	if set to FALSE, the prediction/classification of each sample for each of test.keepX and each comp is returned.
cpus	Number of cpus to use when running the code in parallel.

Details

This tuning function should be used to tune the parameters in the `spls` function (number of components and the number of variables in `keepX` to select).

If `validation = "loo"`, leave-one-out cross-validation is performed. By default `fold`s is set to the number of unique individuals. If `validation = "Mfold"`, M-fold cross-validation is performed. How many folds to generate is selected by specifying the number of folds in `fold`s.

Four measures of accuracy are available: Mean Absolute Error (MAE), Mean Square Error (MSE), Bias and R2. Both MAE and MSE average the model prediction error. MAE measures the average magnitude of the errors without considering their direction. It is the average over the fold test samples of the absolute differences between the Y predictions and the actual Y observations. The MSE also measures the average magnitude of the error. Since the errors are squared before they are averaged, the MSE tends to give a relatively high weight to large errors. The Bias is the average of the differences between the Y predictions and the actual Y observations and the R2 is the correlation between the predictions and the observations. All those measures are averaged across all Y variables in the PLS2 case. We are still improving the function to tune an sPLS2 model, contact us for more details and examples.

The function outputs the optimal number of components that achieve the best performance based on the chosen measure of accuracy. The assessment is data-driven and similar to the process detailed in (Rohart et al., 2016), where one-sided t-tests assess whether there is a gain in performance when adding a component to the model.

See also `?perf` for more details.

Value

A list that contains:

<code>error.rate</code>	returns the prediction error for each <code>test.keepX</code> on each component, averaged across all repeats and subsampling folds. Standard deviation is also output. All error rates are also available as a list.
<code>choice.keepX</code>	returns the number of variables selected (optimal <code>keepX</code>) on each component.
<code>choice.ncomp</code>	returns the optimal number of components for the model fitted with <code>\$choice.keepX</code> and <code>\$choice.keepY</code>
<code>measure</code>	reminds which criterion was used
<code>predict</code>	Prediction values for each sample, each <code>test.keepX</code> , <code>test.keepY</code> , each comp and each repeat. Only if <code>light.output=FALSE</code>

Examples

```
data(liver.toxicity)
X <- liver.toxicity$gene
Y <- liver.toxicity$clinic

## Not run:
tune = tune.spls(X, Y, ncomp=4, test.keepX = c(5,10,15), measure = "MSE",
nrepeat=3, progressBar = TRUE)

tune$choice.ncomp
tune$choice.keepX

# plot the results
plot(tune)

## End(Not run)
```

Description

Computes M-fold or Leave-One-Out Cross-Validation scores on a user-input grid to determine optimal values for the sparsity parameters in `splsda`.

Usage

```
tune.splsda(X, Y, ncomp = 1,
  test.keepX = c(5, 10, 15), already.tested.X, validation = "Mfold",
  folds = 10, dist = "max.dist", measure = "BER", scale = TRUE, auc = FALSE,
  progressBar = TRUE, tol = 1e-06, max.iter = 100, near.zero.var = FALSE,
  nrepeat = 1, logratio = c('none', 'CLR'), multilevel = NULL, light.output = TRUE, cpus)
```

Arguments

<code>X</code>	numeric matrix of predictors. NAs are allowed.
<code>Y</code>	if(<code>method = 'spls'</code>) numeric vector or matrix of continuous responses (for multi-response models) NAs are allowed.
<code>ncomp</code>	the number of components to include in the model.
<code>test.keepX</code>	numeric vector for the different number of variables to test from the X data set
<code>already.tested.X</code>	Optional, if <code>ncomp > 1</code> A numeric vector indicating the number of variables to select from the X data set on the firsts components.
<code>validation</code>	character. What kind of (internal) validation to use, matching one of "Mfold" or "loo" (see below). Default is "Mfold".
<code>folds</code>	the folds in the Mfold cross-validation. See Details.
<code>dist</code>	distance metric to use for <code>splsda</code> to estimate the classification error rate, should be a subset of "centroids.dist", "mahalanobis.dist" or "max.dist" (see Details).
<code>measure</code>	Two misclassification measure are available: overall misclassification error <code>overall</code> or the Balanced Error Rate <code>BER</code>
<code>scale</code>	boolean. If <code>scale = TRUE</code> , each block is standardized to zero means and unit variances (default: <code>TRUE</code>)
<code>auc</code>	if <code>TRUE</code> calculate the Area Under the Curve (AUC) performance of the model.
<code>progressBar</code>	by default set to <code>TRUE</code> to output the progress bar of the computation.
<code>tol</code>	Convergence stopping value.
<code>max.iter</code>	integer, the maximum number of iterations.
<code>near.zero.var</code>	boolean, see the internal <code>nearZeroVar</code> function (should be set to <code>TRUE</code> in particular for data with many zero values). Default value is <code>FALSE</code>
<code>nrepeat</code>	Number of times the Cross-Validation process is repeated.
<code>logratio</code>	one of ('none', 'CLR'). Default to 'none'

<code>multilevel</code>	Design matrix for multilevel analysis (for repeated measurements) that indicates the repeated measures on each individual, i.e. the individuals ID. See Details.
<code>light.output</code>	if set to FALSE, the prediction/classification of each sample for each of <code>test.keepX</code> and each comp is returned.
<code>cpus</code>	Number of cpus to use when running the code in parallel.

Details

This tuning function should be used to tune the parameters in the `splsda` function (number of components and number of variables in `keepX` to select).

For a sPLS-DA, M-fold or LOO cross-validation is performed with stratified subsampling where all classes are represented in each fold.

If `validation = "loo"`, leave-one-out cross-validation is performed. By default `fold` is set to the number of unique individuals.

The function outputs the optimal number of components that achieve the best performance based on the overall error rate or BER. The assessment is data-driven and similar to the process detailed in (Rohart et al., 2016), where one-sided t-tests assess whether there is a gain in performance when adding a component to the model. Our experience has shown that in most case, the optimal number of components is the number of categories in $Y - 1$, but it is worth tuning a few extra components to check (see our website and case studies for more details).

For sPLS-DA multilevel one-factor analysis, M-fold or LOO cross-validation is performed where all repeated measurements of one sample are in the same fold. Note that `logratio` transform and the multilevel analysis are performed internally and independently on the training and test set.

For a sPLS-DA multilevel two-factor analysis, the correlation between components from the within-subject variation of X and the cond matrix is computed on the whole data set. The reason why we cannot obtain a cross-validation error rate as for the sPLS-DA one-factor analysis is because of the difficulty to decompose and predict the within matrices within each fold.

For a sPLS two-factor analysis a sPLS canonical mode is run, and the correlation between components from the within-subject variation of X and Y is computed on the whole data set.

If `validation = "Mfold"`, M-fold cross-validation is performed. How many folds to generate is selected by specifying the number of folds in `fold`.

If `auc = TRUE` and there are more than 2 categories in Y , the Area Under the Curve is averaged using one-vs-all comparison. Note however that the AUC criteria may not be particularly insightful as the prediction threshold we use in sPLS-DA differs from an AUC threshold (sPLS-DA relies on prediction distances for predictions, see `?predict.splsda` for more details) and the supplemental material of the mixOmics article (Rohart et al. 2017).

BER is appropriate in case of an unbalanced number of samples per class as it calculates the average proportion of wrongly classified samples in each class, weighted by the number of samples in each class. BER is less biased towards majority classes during the performance assessment.

More details about the prediction distances in `?predict` and the supplemental material of the mixOmics article (Rohart et al. 2017).

Value

Depending on the type of analysis performed, a list that contains:

<code>error.rate</code>	returns the prediction error for each <code>test.keepX</code> on each component, averaged across all repeats and subsampling folds. Standard deviation is also output. All error rates are also available as a list.
-------------------------	--

choice.keepX	returns the number of variables selected (optimal keepX) on each component.
choice.ncomp	returns the optimal number of components for the model fitted with \$choice.keepX
error.rate.class	returns the error rate for each level of Y and for each component computed with the optimal keepX
predict	Prediction values for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE
class	Predicted class for each sample, each test.keepX, each comp and each repeat. Only if light.output=FALSE
auc	AUC mean and standard deviation if the number of categories in Y is greater than 2, see details above. Only if auc = TRUE
cor.value	only if multilevel analysis with 2 factors: correlation between latent variables.

Examples

```
## First example: analysis with sPLS-DA

data(breast.tumors)
X = breast.tumors$gene.exp
Y = as.factor(breast.tumors$sample$treatment)
tune = tune.splsda(X, Y, ncomp = 1, nrepeat = 10, logratio = "none",
test.keepX = c(5, 10, 15), folds = 10, dist = "max.dist",
progressBar = TRUE)

## Not run:

# 5 components, optimising 'keepX' and 'ncomp'
tune = tune.splsda(X, Y, ncomp = 5, test.keepX = c(5, 10, 15),
folds = 10, dist = "max.dist", nrepeat = 5, progressBar = TRUE)

tune$choice.ncomp
tune$choice.keepX
plot(tune)

## only tune component 3 and 4
# keeping 5 and 10 variables on the first two components respectively

tune = tune.splsda(X = X, Y = Y, ncomp = 4,
```

```

already.tested.X = c(5,10),
test.keepX = seq(1,10,2), progressBar = TRUE)

## Second example: multilevel one-factor analysis with sPLS-DA

data(vac18)
X = vac18$genes
Y = vac18$stimulation
# sample indicates the repeated measurements
design = data.frame(sample = vac18$sample)

tune = tune.splsda(X, Y = Y, ncomp = 3, nrepeat = 10, logratio = "none",
test.keepX = c(5,50,100), folds = 10, dist = "max.dist", multilevel = design)

## End(Not run)

```

tune.splslevel

Tuning functions for multilevel sPLS method

Description

For a multilevel spls analysis, the tuning criterion is based on the maximisation of the correlation between the components from both data sets

Usage

```

tune.splslevel(X, Y, multilevel, ncomp = NULL,
mode = "regression",
test.keepX = rep(ncol(X), ncomp),
test.keepY = rep(ncol(Y), ncomp),
already.tested.X = NULL,
already.tested.Y = NULL)

```

Arguments

X	numeric matrix of predictors. NAs are allowed.
Y	if(method = 'spls') numeric vector or matrix of continuous responses (for multi-response models) NAs are allowed.
multilevel	Design matrix for multilevel analysis (for repeated measurements) that indicates the repeated measures on each individual, i.e. the individuals ID. See Details.
ncomp	the number of components to include in the model.
mode	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic".
test.keepX	numeric vector for the different number of variables to test from the X data set
test.keepY	numeric vector for the different number of variables to test from the Y data set

already.tested.X

Optional, if `ncomp > 1` A numeric vector indicating the number of variables to select from the X data set on the firsts components.

already.tested.Y

Optional, if `ncomp > 1` A numeric vector indicating the number of variables to select from the Y data set on the firsts components.

Details

For a multilevel spls analysis, the tuning criterion is based on the maximisation of the correlation between the components from both data sets

Value

`cor.value` correlation between latent variables

Author(s)

Kim-Anh Lê Cao, Benoit Gautier, Francois Bartolo, Florian Rohart.

Examples

```
data(liver.toxicity)
# note: we made up those data, pretending they are repeated measurements
repeat.indiv <- c(1, 2, 1, 2, 1, 2, 1, 2, 3, 3, 4, 3, 4, 3, 4, 4, 5, 6, 5, 5,
6, 5, 6, 7, 7, 8, 6, 7, 8, 7, 8, 8, 9, 10, 9, 10, 11, 9, 9,
10, 11, 12, 12, 10, 11, 12, 11, 12, 13, 14, 13, 14, 13, 14,
13, 14, 15, 16, 15, 16, 15, 16, 15, 16)
summary(as.factor(repeat.indiv)) # 16 rats, 4 measurements each

# this is a spls (unsupervised analysis) so no need to mention any factor in design
# we only perform a one level variation split
design <- data.frame(sample = repeat.indiv)

tune.splslevel(X = liver.toxicity$gene,
Y=liver.toxicity$clinic,
multilevel = design,
test.keepX = c(5,10,15),
test.keepY = c(1,2,5),
ncomp = 1)
```

unmap

*Dummy matrix for an outcome factor***Description**

Converts a class or group vector or factor into a matrix of indicator variables.

Usage

```
unmap(classification, groups=NULL, noise=NULL)
```

Arguments

classification A numeric or character vector or factor. Typically the distinct entries of this vector would represent a classification of observations in a data set.

groups A numeric or character vector indicating the groups from which **classification** is drawn. If not supplied, the default is to assumed to be the unique entries of **classification**.

noise A single numeric or character value used to indicate the value of groups corresponding to noise.

Value

An n by K matrix of $(0, 1)$ indicator variables, where n is the length of samples and K the number of classes in the outcome.

If a noise value of symbol is designated, the corresponding indicator variables are relocated to the last column of the matrix.

Note: - you can remap an unmap vector using the function **map** from the package **mclust**. - this function should be used to unmap an outcome vector as in the non-supervised methods of **mixOmics**. For other supervised analyses such as (s)PLS-DA, (s)gcccaDA this function is used internally.

Examples

```
data(nutrimouse)
Y = unmap(nutrimouse$diet)
Y
data = list(gene = nutrimouse$gene, lipid = nutrimouse$lipid, Y = Y)
# data could then used as an input in wrapper.rgccca, which is not, technically,
# a supervised method, see ??wrapper.rgccca
```

`vac18`*Vaccine study Data*

Description

The data come from a trial evaluating a vaccine based on HIV-1 lipopeptides in HIV-negative volunteers. The vaccine (HIV-1 LIPO-5 ANRS vaccine) contains five HIV-1 amino acid sequences coding for Gag, Pol and Nef proteins. This data set contains the expression measure of a subset of 1000 genes from purified in vitro stimulated Peripheral Blood Mononuclear Cells from 42 repeated samples (12 unique vaccinated participants) 14 weeks after vaccination, 6 hours after in vitro stimulation by either (1) all the peptides included in the vaccine (LIPO-5), or (2) the Gag peptides included in the vaccine (GAG+) or (3) the Gag peptides not included in the vaccine (GAG-) or (4) without any stimulation (NS).

Usage

```
data(vac18)
```

Format

A list containing the following components:

`gene` data frame with 42 rows and 1000 columns. The expression measure of 1000 genes for the 42 samples (PBMC cells from 12 unique subjects).

`stimulation` is a factor of 42 elements indicating the type of in vitro simulation for each sample.

`sample` is a vector of 42 elements indicating the unique subjects (for example the value '1' correspond to the first patient PBMC cells). Note that the design of this study is unbalanced.

`tab.prob.gene` is a data frame with 1000 rows and 2 columns, indicating the Illumina probe ID and the gene name of the annotated genes.

Details

This is a subset of the original study for illustrative purposes.

Value

none

References

`vac18.simulated`*Simulated data based on the vac18 study for multilevel analysis*

Description

Simulated data based on the vac18 study to illustrate the use of the multilevel analysis for one and two-factor analysis with sPLS-DA. This data set contains the expression simulated of 500 genes.

Usage

```
data(vac18.simulated)
```

Format

A list containing the following components:

`genes` data frame with 48 rows and 500 columns. The simulated expression of 500 genes for 48 subjects.

`sample` a vector indicating the repeated measurements on each unique subject. See Details.

`stimulation` a factor indicating the stimulation condition on each sample.

`time` a factor indicating the time condition on each sample.

Details

In this cross-over design, repeated measurements are performed 12 experiments units (or unique subjects) for each of the 4 stimulations.

The simulation study was based on a mixed effects model (see reference for details). Ten clusters of 100 genes were generated. Amongst those, 4 clusters of genes discriminate the 4 stimulations (denoted LIPO5, GAG+, GAG- and NS) as follows: \-2 gene clusters discriminate (LIPO5, GAG+) versus (GAG-, NS) \-2 gene clusters discriminate LIPO5 versus GAG+, while GAG+ and NS have the same effect \-2 gene clusters discriminate GAG- versus NS, while LIPO5 and GAG+ have the same effect \-the 4 remaining clusters represent noisy signal (no stimulation effect) \

Only a subset of those genes are presented here (to save memory space).

Value

none

vip	<i>Variable Importance in the Projection (VIP)</i>
-----	--

Description

The function `vip` computes the influence on the Y -responses of every predictor X in the model.

Usage

```
vip(object)
```

Arguments

`object` object of class inheriting from "pls", "plsda", "spls" or "splda".

Details

Variable importance in projection (VIP) coefficients reflect the relative importance of each X variable for each X variate in the prediction model. VIP coefficients thus represent the importance of each X variable in fitting both the X - and Y -variates, since the Y -variates are predicted from the X -variates.

VIP allows to classify the X -variables according to their explanatory power of Y . Predictors with large VIP, larger than 1, are the most relevant for explaining Y .

Value

`vip` produces a matrix of VIP coefficients for each X variable (rows) on each variate component (columns).

Y <- linnerud$physiological
linn.pls <- pls(X, Y)

linn.vip <- vip(linn.pls)

barplot(linn.vip,
  beside = TRUE, col = c("lightblue", "mistyrose", "lightcyan"),
  ylim = c(0, 1.7), legend = rownames(linn.vip),
  main = "Variable Importance in the Projection", font.main = 4)
```

withinVariation	<i>Within matrix decomposition for repeated measurements (cross-over design)</i>
-----------------	--

Description

This function is internally called by `pca`, `pls`, `spls`, `plsda` and `splsda` functions for cross-over design data, but can be called independently prior to any kind of multivariate analyses.

Usage

```
withinVariation(X, design)
```

Arguments

<code>X</code>	numeric matrix of predictors. NAs are allowed.
<code>design</code>	a numeric matrix or data frame. The first column indicates the repeated measures on each individual, i.e. the individuals ID. The 2nd and 3rd columns are to split the variation for a 2 level factor.

Details

`withinVariation` function decomposes the Within variation in the X data set. The resulting Xw matrix is then input in the `multilevel` function.

One or two-factor analyses are available.

Value

`withinVariation` simply returns the Xw within matrix, which can be input in the other multivariate approaches already implemented in `mixOmics` (i.e. `spls` or `splsda`, see `multilevel`, but also `pca` or `ipca`).

Examples

```
## Example: one-factor analysis matrix decomposition
#-----
data(vac18)
X <- vac18$genes
# in design we only need to mention the repeated measurements to split the one level variation
design <- data.frame(sample = vac18$sample)

Xw <- withinVariation(X = X, design = design)
# multilevel PCA
res.pca.1level <- pca(Xw, ncomp = 3)

# compare a normal PCA with a multilevel PCA for repeated measurements.
# note: PCA makes the assumptions that all samples are independent,
# so this analysis is flawed and you should use a multilevel PCA instead
res.pca <- pca(X, ncomp = 3)

# set up colors for plotIndiv
col.stim <- c("darkblue", "purple", "green4", "red3")
col.stim <- col.stim[as.numeric(vac18$stimulation)]

# plotIndiv comparing both PCA and PCA multilevel
plotIndiv(res.pca, ind.names = vac18$stimulation, group = col.stim)
title(main = 'PCA ')
plotIndiv(res.pca.1level, ind.names = vac18$stimulation, group = col.stim)
title(main = 'PCA multilevel')
```

 wrapper.rgccca

mixOmics wrapper for Regularised Generalised Canonical Correlation Analysis (rgcca)

Description

Wrapper function to perform Regularized Generalised Canonical Correlation Analysis (rGCCA), a generalised approach for the integration of multiple datasets. For more details, see the `help(rgcca)` from the **RGCCA** package.

Usage

```
wrapper.rgccca(X,
  design = 1 - diag(length(X)),
  tau = rep(1, length(X)),
  ncomp = 1,
  keepX,
  scheme = "horst",
  scale = TRUE,
  init = "svd.single",
  tol = .Machine$double.eps,
  max.iter=1000,
  near.zero.var = FALSE,
  all.outputs = TRUE)
```

Arguments

<code>X</code>	a list of data sets (called 'blocks') matching on the same samples. Data in the list should be arranged in samples x variables. NAs are not allowed.
<code>design</code>	numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strenght of the relationship to be modelled between two blocks using sGCCA; a value of 0 indicates no relationship, 1 is the maximum value. If Y is provided instead of <code>indY</code> , the design matrix is changed to include relationships to Y.
<code>tau</code>	numeric vector of length the number of blocks in X. Each regularization parameter will be applied on each block and takes the value between 0 (no regularisation) and 1. If <code>tau = "optimal"</code> the shrinkage parameters are estimated for each block and each dimension using the Schafer and Strimmer (2005) analytical formula.
<code>ncomp</code>	the number of components to include in the model. Default to 1.
<code>keepX</code>	A vector of same length as X. Each entry <code>keepX[i]</code> is the number of X[[i]]-variables kept in the model.
<code>scheme</code>	Either "horst", "factorial" or "centroid" (Default: "horst").
<code>scale</code>	boolean. If <code>scale = TRUE</code> , each block is standardized to zero means and unit variances (default: TRUE)
<code>init</code>	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single"). Default to "svd.single".
<code>tol</code>	Convergence stopping value.
<code>max.iter</code>	integer, the maximum number of iterations.
<code>near.zero.var</code>	boolean, see the internal <code>nearZeroVar</code> function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
<code>all.outputs</code>	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

This wrapper function performs rGCCA (see **RGCCA**) with $1, \dots, ncomp$ components on each block data set. A supervised or unsupervised model can be run. For a supervised model, the `unmap` function should be used as an input data set. More details can be found on the package **RGCCA**.

Value

`wrapper.rgccca` returns an object of class "rgcca", a list that contains the following components:

<code>data</code>	the input data set (as a list).
<code>design</code>	the input design.
<code>variates</code>	the sgcca components.
<code>loadings</code>	the loadings for each block data set (outer wieght vector).
<code>loadings.star</code>	the laodings, standardised.
<code>tau</code>	the input tau parameter.
<code>scheme</code>	the input schme.

ncomp	the number of components included in the model for each block.
crit	the convergence criterion.
AVE	Indicators of model quality based on the Average Variance Explained (AVE): AVE(for one block), AVE(outer model), AVE(inner model)..
names	list containing the names to be used for individuals and variables.

More details can be found in the references.

```

wrapper.sgcca *mixOmics wrapper for Sparse Generalised Canonical Correlation Analysis (sgcca)*

Description

Wrapper function to perform Sparse Generalised Canonical Correlation Analysis (sGCCA), a generalised approach for the integration of multiple datasets. For more details, see the `help(sgcca)` from the **RGCCA** package.

Usage

```
wrapper.sgcca(X,
  design = 1 - diag(length(X)),
  penalty = NULL,
  ncomp = 1,
  keepX,
  scheme = "horst",
  mode="canonical",
  scale = TRUE,
  init = "svd.single",
  tol = .Machine$double.eps,
  max.iter=1000,
  near.zero.var = FALSE,
  all.outputs = TRUE)
```

Arguments

<code>X</code>	a list of data sets (called 'blocks') matching on the same samples. Data in the list should be arranged in samples x variables. NAs are not allowed.
<code>design</code>	numeric matrix of size (number of blocks in X) x (number of blocks in X) with values between 0 and 1. Each value indicates the strenght of the relationship to be modelled between two blocks using sGCCA; a value of 0 indicates no relationship, 1 is the maximum value. If <code>Y</code> is provided instead of <code>indY</code> , the design matrix is changed to include relationships to <code>Y</code> .
<code>penalty</code>	numeric vector of length the number of blocks in X. Each penalty parameter will be applied on each block and takes the value between 0 (no variable selected) and 1 (all variables included).
<code>ncomp</code>	the number of components to include in the model. Default to 1.
<code>keepX</code>	A vector of same length as X. Each entry <code>keepX[i]</code> is the number of X[[i]]-variables kept in the model.
<code>scheme</code>	Either "horst", "factorial" or "centroid" (Default: "horst").
<code>mode</code>	character string. What type of algorithm to use, (partially) matching one of "regression", "canonical", "invariant" or "classic". See Details.
<code>scale</code>	boolean. If <code>scale = TRUE</code> , each block is standardized to zero means and unit variances (default: TRUE)
<code>init</code>	Mode of initialization use in the algorithm, either by Singular Value Decomposition of the product of each block of X with Y ("svd") or each block independently ("svd.single") . Default to "svd.single".

tol	Convergence stopping value.
max.iter	integer, the maximum number of iterations.
near.zero.var	boolean, see the internal nearZeroVar function (should be set to TRUE in particular for data with many zero values). Setting this argument to FALSE (when appropriate) will speed up the computations. Default value is FALSE
all.outputs	boolean. Computation can be faster when some specific (and non-essential) outputs are not calculated. Default = TRUE.

Details

This wrapper function performs sGCCA (see **RGCCA**) with $1, \dots, ncomp$ components on each block data set. A supervised or unsupervised model can be run. For a supervised model, the [unmap](#) function should be used as an input data set. More details can be found on the package **RGCCA**.

Note that this function is the same as [block.spls](#) with different default arguments.

More details about the PLS modes in `?pls`.

Value

`wrapper.sgcca` returns an object of class "sgcca", a list that contains the following components:

data	the input data set (as a list).
design	the input design.
variates	the sgcca components.
loadings	the loadings for each block data set (outer wieght vector).
loadings.star	the laodings, standardised.
penalty	the input penalty parameter.
scheme	the input schme.
ncomp	the number of components included in the model for each block.
crit	the convergence criterion.
AVE	Indicators of model quality based on the Average Variance Explained (AVE): AVE(for one block), AVE(outer model), AVE(inner model)..
names	list containing the names to be used for individuals and variables.

More details can be found in the references.

Examples

```

data(nutrimouse)
# need to unmap the Y factor diet if you pretend this is not a classification pb.
# see also the function block.splsda for discriminant analysis where you dont
# need to unmap Y.
Y = unmap(nutrimouse$diet)
data = list(gene = nutrimouse$gene, lipid = nutrimouse$lipid, Y = Y)
# with this design, gene expression and lipids are connected to the diet factor
# design = matrix(c(0,0,1,
#                   0,0,1,
#                   1,1,0), ncol = 3, nrow = 3, byrow = TRUE)

# with this design, gene expression and lipids are connected to the diet factor
# and gene expression and lipids are also connected
design = matrix(c(0,1,1,
                 1,0,1,
                 1,1,0), ncol = 3, nrow = 3, byrow = TRUE)

#note: the penalty parameters will need to be tuned
wrap.result.sgcca = wrapper.sgcca(X = data, design = design, penalty = c(.3,.5, 1),
ncomp = 2,
scheme = "centroid")
wrap.result.sgcca
#did the algo converge?
wrap.result.sgcca$crit # yes

```

yeast

Yeast metabolomic study

Description

Two *Saccharomyces Cerevisiae* strains were compared under two different environmental conditions, 37 metabolites expression are measured.

Usage

```
data(yeast)
```

Format

A list containing the following components:

data data matrix with 55 rows and 37 columns. Each row represents an experimental sample, and each column a single metabolite.

strain a factor containing the type of strain (MT or WT).

condition a factor containing the type of environmental condition (AER or ANA).

strain.condition a crossed factor between strain and condition.

Details

In this study, two *Saccharomyces cerevisiae* strains were used - wild-type (WT) and mutant (MT), and were carried out in batch cultures under two different environmental conditions, aerobic (AER) and anaerobic (ANA) in standard mineral media with glucose as the sole carbon source. After normalization and pre processing, the metabolomic data results in 37 metabolites and 55 samples which include 13 MT-AER, 14 MT-ANA, 15 WT-AER and 13 WT-ANA samples

Value

none
