# Package 'msPurity'

October 16, 2019

Type Package

**Title** Automated Evaluation of Precursor Ion Purity for Mass Spectrometry Based Fragmentation in Metabolomics

**Version** 1.10.0 **Date** 2019-04-28

Author Thomas N. Lawson, Ralf Weber, Martin Jones, Mark Viant, Warwick Dunn

Maintainer Thomas N. Lawson <thomas.nigel.lawson@gmail.com>

**Description** msPurity R package was developed to:

- 1) Assess the spectral quality of fragmentation spectra by evaluating the "precursor ion purity".
- 2) Process fragmentation spectra.
- 3) Perform spectral matching.

What is precursor ion purity? -What we call ``Precursor ion purity" is a measure of the contribution of a selected precursor peak in an isolation window used for fragmentation. The simple calculation involves dividing the intensity of the selected precursor peak by the total intensity of the isolation window. When assessing MS/MS spectra this calculation is done before and after the MS/MS scan of interest and the purity is interpolated at the recorded time of the MS/MS acquisition. Additionally, isotopic peaks can be removed, low abundance peaks are removed that are thought to have limited contribution to the resulting MS/MS spectra and the isolation efficiency of the mass spectrometer can be used to normalise the intensities used for the calculation.

**Encoding** UTF-8 **License** GPL (>= 2)

LazyData TRUE

BugReports https://github.com/computational-metabolomics/msPurity/issues/new

**Depends** Rcpp

**Imports** plyr, dplyr, dbplyr, magrittr, foreach, parallel, doSNOW, stringr, mzR, reshape2, fastcluster, ggplot2, DBI, RSQLite, uuid, jsonlite, KEGGREST

assessPuritySingle Assess the purity of a single LC-MS/MS or DI-MS/MS file

# Description

Given a filepath to an mzML file the precursor purity for any MS/MS scans will be outputed into a dataframe

# Usage

```
assessPuritySingle(filepth, fileid = NA, mostIntense = FALSE,
 nearest = TRUE, offsets = NA, cores = 1, plotP = FALSE,
 plotdir = NULL, interpol = "linear", iwNorm = FALSE,
 iwNormFun = NULL, ilim = 0, mzRback = "pwiz", isotopes = TRUE,
 im = NULL)
```

# **Arguments**

filepth	character; mzML file path for MS/MS spectra
fileid	numeric; adds a fileid column (primarily for internal use for msPurity)
mostIntense	boolean; True if the most intense peak is used for calculation. False if the centered peak is used
nearest	boolean; True if the peak selected is as the nearest MS1 scan. If False then the preceding scan is used
offsets	vector; Overide the isolation offsets found in the mzML filee.g. c(0.5, 0.5)
cores	numeric; Number of cores to use
plotP	boolean; If TRUE a plot of the purity is to be saved
plotdir	vector; If plotP is TRUE plots will be saved to this directory
interpol	character; Type of interolation to be performed "linear", "spline" or "none"
iwNorm	boolean; If TRUE then the intensity of the isolation window will be normalised based on the iwNormFun function
iwNormFun	function; A function to normalise the isolation window intensity. The default function is very generalised and just accounts for edge effects
ilim	numeric; All peaks less than this percentage of the target peak will be removed from the purity calculation, default is $5\%$ $(0.05)$
mzRback	character; Backend to use for mzR parsing
isotopes	boolean; TRUE if isotopes are to be removed
im	matrix; Isotope matrix, default removes C13 isotopes (single, double and triple bonds)

#### Value

a dataframe of the purity score of the ms/ms spectra

#### See Also

```
purityA
```

#### **Examples**

```
filepth <- system.file("extdata", "lcms", "mzML", "LCMSMS_1.mzML", package="msPurityData")
puritydf <- assessPuritySingle(filepth)</pre>
```

```
averageAllFragSpectra,purityA-method

Using a purityA object, average and filter MS/MS spectra for each XCMS feature within and across MS data files (ignoring intra and inter relationships)

# **Description**

#### General

Average and filter fragmentation spectra for each XCMS feature within and across MS data files (ignoring intra and inter relationships).

The averaging is performed using hierarchical clustering of the m/z values of each peaks, where m/z values within a set ppm tolerance will be clustered. The clustered peaks are then averaged (or summed).

The fragmentation can be filtered on the averaged spectra (with the arguments snr, rsd, minfrac, ra)

# Example LC-MS/MS processing workflow

- Purity assessments
  - (mzML files) -> purityA -> (pa)
- · XCMS processing
  - (mzML files) -> xcms.xcmsSet -> xcms.merge -> xcms.group -> xcms.retcor -> xcms.group -> (xset)
- · Fragmentation processing
  - (xset, pa) -> frag4feature -> filterFragSpectra -> averageAllFragSpectra -> createDatabase
     -> spectralMatching -> (sqlite spectral database)

#### Usage

```
## S4 method for signature 'purityA'
averageAllFragSpectra(pa, minfrac = 0.5,
   minnum = 1, ppm = 5, snr = 0, ra = 0, av = "median",
   sumi = TRUE, rmp = FALSE, cores = 1)
```

#### **Arguments**

ра	object; purityA object
minfrac	numeric;minimum ratio of the peak fraction (peak count / total peaks) across all (ignoring intra and inter relationships)
minnum	numeric; minimum number of times peak is present across all fragmentation spectra (ignoring intra and inter relationships)
ppm	numeric; ppm threshold to average across all scans (ignoring intra and inter relationships)
snr	numeric; minimum signal-to-noise of the peak across all (ignoring intra and inter relationships)
ra	numeric; minimum relative abundance of the peak fraction across all (ignoring intra and inter relationships)
av	character; type of averaging to use (median or mean)
sumi	boolean; TRUE if the intensity for each peak is summed across averaged spectra
rmp	boolean; TRUE if peaks are to be removed that do not meet the threshold criteria. Otherwise they will just be flagged
cores	numeric; Number of cores for multiprocessing

#### Value

Returns a purityA object (pa) with the following slots now with data

- pa@av\_spectra: the average spectra is recorded here stored as a list. E.g. pa@av\_spectra\$1\$av\_all would give the average spectra for grouped feature 1.
- pa@av\_all\_params: The parameters used are recorded here

Each spectra in the av\_spectra list contains the following columns:

- cl: id of clustered (averaged) peak
- mz: average m/z
- i: average intensity
- snr: average signal to noise ratio
- rsd: relative standard deviation
- count: number of clustered peaks
- total: total number of potential scans to be used for averaging
- inPurity: average precursor ion purity
- ra: average relative abundance
- frac: the fraction of clustered peaks (e.g. the count/total)
- snr\_pass\_flag: TRUE if snr threshold criteria met
- minfrac\_pass\_flag: TRUE if minfrac threshold criteria
- ra\_pass\_flag: TRUE if ra threshold criteria met
- pass\_flag: TRUE if all threshold criteria met

### **Examples**

```
#msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pa
#xset <- xcms::xcmsSet(msmsPths, nSlaves = 1)
#xset <- xcms::group(xset)

#xset <- xcms::retcor(xset)

#xset <- xcms::group(xset)

#pa <- purityA(msmsPths, interpol = "linear")
#pa <- frag4feature(pa, xset)
#pa <- filterFragSpectra(pa)
pa <- readRDS(system.file("extdata", "tests", "purityA", "3_filterFragSpectra_pa.rds", package="msPurity"))
pa <- averageAllFragSpectra(pa)</pre>
```

averageInterFragSpectra,purityA-method

Using a purityA object, average and filter fragmentation spectra for each XCMS feature across multiple MS data files

#### **Description**

#### General

Average and filter fragmentation spectra for each XCMS feature across MS data files. This can only be run after averageIntraFragSpectra has been used.

The averaging is performed using hierarchical clustering of the m/z values of each peaks, where m/z values within a set ppm tolerance will be clustered. The clustered peaks are then averaged (or summed).

The fragmentation can be filtered on the averaged spectra (with the arguments snr, rsd, minfrac and ra)

# Example LC-MS/MS processing workflow

- Purity assessments
  - (mzML files) -> purityA -> (pa)
- · XCMS processing
  - (mzML files) -> xcms.xcmsSet -> xcms.merge -> xcms.group -> xcms.retcor -> xcms.group -> (xset)
- · Fragmentation processing
  - (xset, pa) -> frag4feature -> filterFragSpectra -> averageIntraFragSpectra -> averageInterFragSpectra -> createDatabase -> spectralMatching -> (sqlite spectral database)

#### Usage

```
## S4 method for signature 'purityA'
averageInterFragSpectra(pa, minfrac = 0.5,
   minnum = 1, ppm = 5, snr = 0, ra = 0, av = "median",
   sumi = TRUE, rmp = FALSE, cores = 1)
```

# Arguments

ра	object; purityA object
minfrac	numeric; minimum ratio of the peak fraction (peak count / total peaks) across files
minnum	numeric; minimum number of times peak is present across fragmentation spectra across files
ppm	numeric; ppm threshold to average across files
snr	numeric; minimum signal-to-noise of the peak across files
ra	numeric; minimum relative abundance of the peak across files
av	character; type of averaging to use (median or mean)
sumi	boolean; TRUE if the intensity for each peak is summed across averaged spectra
rmp	boolean; TRUE if peaks are to be removed that do not meet the threshold criteria. Otherwise they will just be flagged
cores	numeric; Number of cores for multiprocessing

#### Value

Returns a purityA object (pa) with the following slots now with data

- pa@av\_spectra: the average spectra is recorded here stored as a list. e.g. "pa@av\_spectra\$1\$av\_inter" would give the average spectra for grouped feature 1
- pa@av\_intra\_params: The parameters used are recorded here

Each spectra in the av\_spectra list contains the following columns: \*

- cl: id of clustered (averaged) peak
- mz: average m/z
- i: average intensity
- snr: average signal to noise ratio
- rsd: relative standard deviation
- count: number of clustered peaks
- total: total number of potential scans to be used for averaging
- inPurity: average precursor ion purity
- ra: average relative abundance
- frac: the fraction of clustered peaks (e.g. the count/total)
- snr\_pass\_flag: TRUE if snr threshold criteria met
- minfrac\_pass\_flag: TRUE if minfrac threshold criteria
- ra\_pass\_flag: TRUE if ra threshold criteria met
- pass\_flag: TRUE if all threshold criteria met

#### **Examples**

```
#msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pa
#xset <- xcms::xcmsSet(msmsPths, nSlaves = 1)
#xset <- xcms::group(xset)

#xset <- xcms::retcor(xset)

#xset <- xcms::group(xset)

#pa <- purityA(msmsPths, interpol = "linear")

#pa <- frag4feature(pa, xset)

#pa <- averageIntraFragSpectra(pa)
pa <- readRDS(system.file("extdata", "tests", "purityA", "4_averageIntraFragSpectra_no_filter_pa.rds", packag
pa <- averageInterFragSpectra(pa)</pre>
```

averageIntraFragSpectra,purityA-method

Using a purityA object, average and filter fragmentation spectra for each XCMS feature within a MS data file

#### **Description**

#### General

Average and filter fragmentation spectra for each XCMS feature within a MS data file.

The averaging is performed using hierarchical clustering of the m/z values of each peaks, where m/z values within a set ppm tolerance will be clustered. The clustered peaks are then averaged (or summed).

The fragmentation can be filtered on the averaged spectra (with the arguments snr, rsd, minfrac and ra)

# Example LC-MS/MS processing workflow

- Purity assessments
  - (mzML files) -> purityA -> (pa)
- · XCMS processing
  - (mzML files) -> xcms.xcmsSet -> xcms.merge -> xcms.group -> xcms.retcor -> xcms.group -> (xset)
- Fragmentation processing
  - (xset, pa) -> frag4feature -> filterFragSpectra -> averageIntraFragSpectra -> averageIntraFragSpectra -> createDatabase -> spectralMatching -> (sqlite spectral database)

#### Usage

```
## S4 method for signature 'purityA'
averageIntraFragSpectra(pa, minfrac = 0.5,
   minnum = 1, ppm = 5, snr = 0, ra = 0, av = "median",
   sumi = TRUE, rmp = FALSE, cores = 1)
```

#### **Arguments**

ра	object; purityA object
minfrac	numeric; minimum ratio of the peak fraction (peak count / total peaks) within each file
minnum	numeric; minimum number of times peak is present across fragmentation spectra within each file
ppm	numeric; ppm threshold to average within each file
snr	numeric; minimum signal-to-noise of the peak within each file
ra	numeric; minimum relative abundance of the peak within each file
av	character; type of averaging to use (median or mean)
sumi	boolean; TRUE if the intensity for each peak is summed across averaged spectra
rmp	boolean; TRUE if peaks are to be removed that do not meet the threshold criteria. Otherwise they will just be flagged
cores	numeric; Number of cores for multiprocessing

#### Value

Returns a purityA object (pa) with the following slots now with data

- pa@av\_spectra: the average spectra is recorded here stored as a list. e.g. "pa@av\_spectra\$1\$av\_intra\$1" would give the average spectra for grouped feature 1 and for file 1.
- pa@av\_intra\_params: The parameters used are recorded here

Each spectra in the av\_spectra list contains the following columns:

- cl: id of clustered (averaged) peak
- mz: average m/z
- i: average intensity
- snr: average signal to noise ratio
- rsd: relative standard deviation
- count: number of clustered peaks
- total: total number of potential scans to be used for averaging
- inPurity: average precursor ion purity
- ra: average relative abundance
- frac: the fraction of clustered peaks (e.g. the count/total)
- snr\_pass\_flag: TRUE if snr threshold criteria met
- minfrac\_pass\_flag: TRUE if minfrac threshold criteria
- ra\_pass\_flag: TRUE if ra threshold criteria met
- pass\_flag: TRUE if all threshold criteria met

#### **Examples**

```
#msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pa
#xset <- xcms::xcmsSet(msmsPths, nSlaves = 1)
#xset <- xcms::group(xset)

#xset <- xcms::retcor(xset)

#xset <- xcms::group(xset)

#pa <- purityA(msmsPths)
#pa <- frag4feature(pa, xset)
pa <- readRDS(system.file("extdata", "tests", "purityA", "2_frag4feature_pa.rds", package="msPurity"))
pa <- averageIntraFragSpectra(pa)</pre>
```

averageSpectra, purityD-method

Using purityD object, calculates to average mz, intensity and signal-to-noise of multiple scans from multiple MS datafiles (mzML or .csv)

#### **Description**

Uses a purityD object with references to multiple MS files. For each file: Averages multiple scans together, see averageSpectraSingle for more information

#### Usage

```
## S4 method for signature 'purityD'
averageSpectra(Object, rtscn = "all",
    scanRange = NA, timeRange = NA, clustType = "hc", ppm = 1.5,
    snthr = 3, av = "median", missingV = "zero", minfrac = 0.6667,
    normTIC = FALSE, snMeth = "median")
```

# **Arguments**

snMeth

Object	object; purityD object
rtscn	character; Whether it is scans or retention time to be filtered. Use "all" if all scans to be used. ['rt', 'scns', 'all']
scanRange	vector; Scan range (if rtscn='scns') e.g. c(40, 69)
timeRange	vector; Time range (if rtscn='rt) e.g. c(10.3, 400.8) (only if using mzML file)
clustType	character; Type of clustering used either Hierarchical or just simple 1D grouping ['hc', 'simple']
ppm	numeric; The ppm error to cluster mz together
snthr	numeric; Signal to noise ratio threshold
av	character; What type of averaging to do between peaks
missingV	character; What to do with missing values (zero or ignore)
minfrac	numeric; Min fraction of scans with a grouped peak to be an accepted averaged peak
normTIC	boolean; If TRUE then RSD calculation will use the normalised intensity (intensity divided by TIC) if FALSE will use standard intensity

applicable when using the csvFile parameter as TRUE

character; Type of snMethod to use ['mean', 'median', 'precalc']. Precalc only

averageSpectraSingle 11

#### Value

purityD object with averaged spectra

#### See Also

```
averageSpectraSingle
```

#### **Examples**

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)
ppDIMS <- purityD(fileList=inDF, cores=1, mzML=TRUE)
ppDIMS <- averageSpectra(ppDIMS)</pre>
```

averageSpectraSingle Calculates to average mz, intensity and signal-to-noise of multiple scans from 1 MS datafile (mzML or .csv)

# Description

Averages multiple scans of mass spectrometry data together. Each scan consisting of a minimum of intensity and mz values.

Works for either mzML or a .csv file consisting of mz, i, scanid, (optional: noise, backgroun, snr)

Signal-to-noise (SNR) can be calculated a number of ways. Default is to calculate the SN for every scan as the "Intensity of peak / the median intensity of the scan".

Alternatively if using a .csv file as input (and assigning the csvFile parameter to TRUE), a precalculated SNR can be one of the columns. The precalculated SNR can then be chosen by using the option 'precalc' for the parameter snMethod

The function will work for both LC-MS or DI-MS datasets.

# Usage

```
averageSpectraSingle(filePth, rtscn = "all", scanRange = NA,
  timeRange = NA, clustType = "hc", ppm = 1.5, snthr = 3,
  cores = 1, av = "median", missingV = "ignore", minfrac = 0.6667,
  snMeth = "median", csvFile = FALSE, normTIC = FALSE,
  mzRback = "pwiz", MSFileReader = FALSE)
```

#### Arguments

filePth	character; Path of the file to be processed
rtscn	character; Whether it is scans or retention time to be filtered. Use "all" if all scans to be used. ['rt', 'scns', 'all']
scanRange	vector; Scan range (if rtscn='scns') e.g. c(40, 69)
timeRange	vector; Time range (if rtscn='rt) e.g. c(10.3, 400.8) (only if using mzML file)
clustType	character; Type of clustering used either Hierarchical or just simple 1D grouping ['hc', 'simple']
ppm	numeric; The ppm error to cluster mz together

12 combineAnnotations

snthr	numeric; Signal to noise ratio threshold
cores	numeric; Number of cores used to perform Hierarchical clustering WARNING: memory intensive, default 2
av	character; What type of averaging to do between peaks
missingV	character; What to do with missing values (zero or ignore)
minfrac	numeric; Min fraction of scans with a grouped peak to be an accepted averaged peak
snMeth	character; Type of snMethod to use ['mean', 'median', 'precalc']. Precalc only applicable when using the csvFile parameter as TRUE
csvFile	boolean; A csv file can be used as input. Useful for thermo files where the MSFileReader API can extract peaklist. This can consist of an .csv file with the following columns c('mz', 'i', 'scanid', 'snr')
normTIC	boolean; If TRUE then RSD calculation will use the normalised intensity (intensity divided by TIC) if FALSE will use standard intensity
mzRback	character; Backend to use for mzR parsing
MSFileReader	boolean; Deprecapted. Use csvFile parameter

#### Value

dataframe of the median mz, intensity, signal-to-noise ratio.

# **Examples**

```
mzmlPth <- system.file("extdata", "dims", "mzML", "B02_Daph_TEST_pos.mzML", package="msPurityData")
avP <- averageSpectraSingle(mzmlPth)</pre>
```

combineAnnotations

Combine Annotations

# Description

Combine the annotation results from msPurity spectral matching, MetFrag, Sirius CSI:FingerID and probmetab based on weighted scores for each technique aligning each annotation by inchikey and XCMS grouped feature.

# Usage

```
combineAnnotations(sm_resultPth, metfrag_resultPth = NA,
    sirius_csi_resultPth = NA, probmetab_resultPth = NA,
    weights = list(sm = 0.4, metfrag = 0.25, sirius_csifingerid = 0.25,
    probmetab = 0.1), outPth = NA, silentRestErrors = FALSE)
```

# Arguments

createDatabase 13

# Value

purityA object with slots for fragmentation-XCMS links

#### **Examples**

```
metfrag_resultPth <- system.file("extdata", "external_annotations", "metfrag.tsv", package="msPurity")
# run the standard spectral matching workflow to get the sm_resultPth
sm_resultPth <- system.file("extdata","tests", "sm", "spectralMatching_result.sqlite", package="msPurity")
combined <- combineAnnotations(sm_resultPth, metfrag_resultPth, outPth=file.path(tempdir(), 'combined.sqlite")</pre>
```

createDatabase

Create database

### **Description**

```
** General **
```

Create and SQLite database of an LC-MS(/MS) experiment (replaces the create\_database function).

Schema details can be found here.

# Example LC-MS/MS processing workflow

- Purity assessments
  - (mzML files) -> purityA -> (pa)
- · XCMS processing
  - (mzML files) -> xcms.xcmsSet -> xcms.merge -> xcms.group -> xcms.retcor -> xcms.group -> (xset)
- Fragmentation processing
  - (xset, pa) -> frag4feature -> filterFragSpectra -> averageAllFragSpectra -> createDatabase
     -> spectralMatching -> (sqlite spectral database)

# Usage

```
createDatabase(pa, xset, xsa = NULL, outDir = ".", grpPeaklist = NA,
   dbName = NA, metadata = NA)
```

14 createDatabase

#### **Arguments**

ра	purityA object; Needs to be the same used for frag4feature function
xset	xcms object; Needs to be the same used for frag4feature function (this will be ignored when using xsa parameter)
xsa	CAMERA object (optional); if CAMERA object is used, we ignore the xset parameter input and obtain all information from the xset object nested with the CAMERA xsa object. Adduct and isotope information will be included into the database when using this parameter. The underlying xset object must be the one used for the frag4feature function
outDir	character; Out directory for the SQLite result database
grpPeaklist	dataframe (optional); Can use any peak dataframe. Still needs to be derived from the xset object though
dbName	character (optional); Name of the result database
metadata	list; A list of metadata to add to the s_peak_meta table

#### Value

path to SQLite database and database name

# **Examples**

```
#msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pa</pre>
#xset <- xcms::xcmsSet(msmsPths)</pre>
#xset <- xcms::group(xset)</pre>
#xset <- xcms::retcor(xset)</pre>
#xset <- xcms::group(xset)</pre>
#pa <- purityA(msmsPths)</pre>
#pa <- frag4feature(pa, xset)</pre>
#pa <- filterFragSpectra(pa, allfrag=TRUE)</pre>
#pa <- averageAllFragSpectra(pa)</pre>
#dbPth <- createDatabase(pa, xset, metadata=list('polarity'='positive', 'instrument'='Q-Exactive'))</pre>
# Run from previously generated data:
pa <- readRDS(system.file("extdata", "tests", "purityA", "9_averageAllFragSpectra_with_filter_pa.rds", package xset <- readRDS(system.file("extdata", "tests", "xcms", "msms_only_xset.rds", package="msPurity"))
msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, patrons
pa@fileList[1] <- msmsPths[basename(msmsPths) == "LCMSMS\_1.mzML"] \\
pa@fileList[2] <- msmsPths[basename(msmsPths)=="LCMSMS_2.mzML"]</pre>
xset@filepaths[1] <- msmsPths[basename(msmsPths)=="LCMSMS_1.mzML"]</pre>
xset@filepaths[2] <- msmsPths[basename(msmsPths)=="LCMSMS_2.mzML"]</pre>
td <- tempdir()</pre>
db_pth = createDatabase(pa, xset, outDir = td)
```

```
createMSP, purityA-method
```

Using a purityA object, create an MSP file of fragmentation spectra

# **Description**

# General

Create an MSP file for all the fragmentation spectra that has been linked to an XCMS feature via frag4feature. Can export all the associated scans individually or the averaged fragmentation spectra can be exported.

Additional metadata can be included in a dataframe (each column will be added to metadata of the MSP spectra). The dataframe must contain the column "grpid" corresponding to the XCMS grouped feature.

# Example LC-MS/MS processing workflow

- Purity assessments
  - (mzML files) -> purityA -> (pa)
- XCMS processing
  - (mzML files) -> xcms.xcmsSet -> xcms.merge -> xcms.group -> xcms.retcor -> xcms.group -> (xset)
- Fragmentation processing
  - (xset, pa) -> frag4feature -> filterFragSpectra -> averageIntraFragSpectra -> averageIntraFragSpectra -> createMSP -> (MSP file)

### Usage

```
## S4 method for signature 'purityA'
createMSP(pa, msp_file_pth = NULL, metadata = NULL,
  metadata_cols = NULL, xcms_groupids = NULL, method = "all",
  adduct_split = TRUE, filter = TRUE, msp_schema = "massbank",
  intensity_ra = "intensity_ra")
```

#### **Arguments**

ра	object; purityA object
msp_file_pth	character; Name of the output msp file, if NULL the file "frag_spectra_time stamp.msp" will be created in the current directory
metadata	data.frame; Data frame with additional coumpound infomation to include in msp output
metadata_cols	vector; Column names of meta data to incorporate into name
xcms_groupids	vector; XCMS group id's to extract ms/ms data for
method	character; "all" will export all matching ms/ms spectra to xcms features, "max" will use spectra with the highest inensity, "av_intra" will use the intra file averaged spectra (within file), "av_inter" will use the inter file (across file) averaged spectra, "av_all" will use the averaged spectra (ignoring inter and intra)
adduct_split	boolean; If either "adduct" or MS\$FOCUSED_ION: PRECURSOR_TYPE column is in metadata then each adduct will have it's own MSP spectra. (Useful, if the MSP file will be used for further annotation)

16 create\_database

filter boolean; TRUE if filtered peaks are to be removed

msp\_schema character; Either MassBank (Europe) or MoNA style of MSP file format to be

used ('massbank' or 'mona')

intensity\_ra character; Either 'intensity', 'ra' (relative abundance) or 'intensity\_ra' (intensity

and relative abundance) to be written to the MSP file

#### Value

Returns a MSP file with the selected spectra and metadata

#### **Examples**

```
#msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pa

```

create\_database

Create database [deprecated]

### **Description**

Create and SQLite database of an LC-MS(/MS) experiment msPurity::create\_database is deprecated. Please use msPurity::createDatabase for future use

# Usage

```
create_database(pa, xset, xsa = NULL, out_dir = ".",
  grp_peaklist = NA, db_name = NA)
```

# Arguments

db\_name

ра	purityA object; Needs to be the same used for frag4feature function	
xset	xcms object; Needs to be the same used for frag4feature function (this will be ignored when using xsa parameter)	
xsa	CAMERA object [optional]; if CAMERA object is used, we ignore the xset parameter input and obtain all information from the xset object nested with the CAMERA xsa object. Adduct and isotope information will be included into the database when using this parameter. The underlying xset object must be the one used for the frag4feature function	
out_dir	character; Out directory for the SQLite result database	
grp_peaklist	dataframe [optional]; Can use any peak dataframe. Still needs to be derived from the xset object though	

character [optional]; Name of the result database

#### Value

path to SQLite database and database name

#### **Examples**

```
#msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pa</pre>
#xset <- xcms::xcmsSet(msmsPths)</pre>
#xset <- xcms::group(xset)</pre>
#pa <- purityA(msmsPths)</pre>
#pa <- frag4feature(pa, xset)</pre>
#pa <- averageAllFragSpectra(pa)</pre>
#db_pth <- create_database(pa, xset)</pre>
# Run from previously generated data
pa <- readRDS(system.file("extdata", "tests", "purityA", "9_averageAllFragSpectra_with_filter_pa.rds", packa
xset <- readRDS(system.file("extdata","tests", "xcms", "msms_only_xset.rds", package="msPurity"))</pre>
# Need to ensure the filelists are matching
msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pat
pa@fileList[1] <- msmsPths[basename(msmsPths)=="LCMSMS_1.mzML"]</pre>
pa@fileList[2] <- msmsPths[basename(msmsPths)=="LCMSMS_2.mzML"]</pre>
xset@filepaths[1] <- msmsPths[basename(msmsPths)=="LCMSMS_1.mzML"]</pre>
xset@filepaths[2] <- msmsPths[basename(msmsPths)=="LCMSMS_2.mzML"]</pre>
db_pth <- create_database(pa, xset)</pre>
```

dimsPredictPurity,purityD-method

Using purityD object, assess anticipated purity from a DI-MS run

#### **Description**

Assess the precursor purity of anticpated MS/MS spectra. i.e. it 'predicts' the precursor purity of the DI-MS peaks for a future MS/MS run.

# Usage

```
## S4 method for signature 'purityD'
dimsPredictPurity(Object, ppm = 1.5,
    minOffset = 0.5, maxOffset = 0.5, iwNorm = FALSE,
    iwNormFun = NULL, ilim = 0.05, sampleOnly = FALSE,
    isotopes = TRUE, im = NULL)
```

### **Arguments**

Object object = purityD object

ppm numeric = tolerance for target mz value in each scan

minOffset numeric = isolation window minimum offset maxOffset numeric = isolation window maximum offset

iwNorm boolean = if TRUE then the intensity of the isolation window will be normalised

based on the iwNormFun function

iwNormFun	function = A function to normalise the isolation window intensity. The default function is very generalised and just accounts for edge effects	
ilim	numeric = All peaks less than this percentage of the target peak will be removed from the purity calculation, default is $5\%$ (0.05)	
sampleOnly	boolean = if TRUE will only calculate purity for sample peaklists	
isotopes	boolean = TRUE if isotopes are to be removed	
im	matrix = Isotope matrix, default removes C13 isotopes (single, double and triple	

bonds)

#### Value

```
purityD object with predicted purity of peaks purityD object
```

#### See Also

```
dimsPredictPuritySingle
```

#### **Examples**

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)
ppDIMS <- purityD(fileList=inDF, cores=1, mzML=TRUE)
ppDIMS <- averageSpectra(ppDIMS)
ppDIMS <- filterp(ppDIMS)
ppDIMS <- subtract(ppDIMS)
ppDIMS <- dimsPredictPurity(ppDIMS)</pre>
```

dimsPredictPuritySingle

Predict the precursor purity from a DI-MS dataset

# **Description**

Given a an DI-MS dataset (either mzML or .csv file) calculate the predicted purity for a vector of mz values.

Calculated at a given offset e.g. for 0.5 +/- Da the minOffset would be 0.5 and the maxOffset of 0.5.

A ppm tolerance is used to find the target mz value in each scan.

# Usage

```
dimsPredictPuritySingle(mztargets, filepth, minOffset = 0.5,
   maxOffset = 0.5, ppm = 2.5, mzML = TRUE, iwNorm = FALSE,
   iwNormFun = NULL, ilim = 0.05, mzRback = "pwiz", isotopes = TRUE,
   im = NULL, sim = FALSE)
```

# **Arguments**

mztargets	vector = mz targets to get predicted purity for		
filepth	character = mzML file path or .csv file path		
minOffset	numeric = isolation window minimum offset		
maxOffset	numeric = isolation window maximum offset		
ppm	numeric = tolerance for target mz value in each scan		
mzML	boolean = Whether an mzML file is to be used or .csv file (TRUE == mzML)		
iwNorm	boolean = if TRUE then the intensity of the isolation window will be normalised based on the iwNormFun function		
iwNormFun	function = A function to normalise the isolation window intensity. The default function is very generalised and just accounts for edge effects		
ilim	numeric = All peaks less than this percentage of the target peak will be removed from the purity calculation, default is $5\%\ (0.05)$		
mzRback	character = backend to use for mzR parsing		
isotopes	boolean = TRUE if isotopes are to be removed		
im	matrix = Isotope matrix, default removes C13 isotopes (single, double and triple bonds)		
sim	boolean = TRUE if file is from sim stitch experiment. Default FALSE		

#### Value

a dataframe of the target mz values and the predicted purity score

# **Examples**

```
mzmlPth <- system.file("extdata", "dims", "mzML", "B02_Daph_TEST_pos.mzML", package="msPurityData")
predicted <- dimsPredictPuritySingle(c(173.0806, 216.1045), filepth=mzmlPth, minOffset=0.5, maxOffset=0.5, package="msPurityData")</pre>
```

filterFragSpectra,purityA-method

Filter fragmentations spectra associated with an XCMS feature

# Description

#### General

Flag and filter features based on signal-to-noise ratio, relative abundance, intensity threshold and precursor ion purity of precursor.

# Example LC-MS/MS processing workflow

The purityA object can be used for further processing including linking the fragmentation spectra to XCMS features, averaging fragmentation, database creation and spectral matching (from the created database). See below for an example workflow

- Purity assessments
  - (mzML files) -> purityA -> (pa)
- · XCMS processing

- (mzML files) -> xcms.xcmsSet -> xcms.merge -> xcms.group -> xcms.retcor -> xcms.group -> (xset)
- · Fragmentation processing
  - (xset, pa) -> frag4feature -> filterFragSpectra -> averageAllFragSpectra -> createDatabase
     -> spectralMatching -> (sqlite spectral database)

#### **Usage**

```
## S4 method for signature 'purityA'
filterFragSpectra(pa, ilim = 0, plim = 0.8,
   ra = 0, snr = 3, rmp = FALSE, snmeth = "median",
   allfrag = FALSE)
```

#### **Arguments**

ра	object; purityA object	
ilim	numeric; min intensity of a peak	
plim	numeric; min precursor ion purity of the associated precursor for fragmentation spectra scan	
ra	numeric; minimum relative abundance of a peak	
snr	numeric; minimum signal-to-noise of a peak peak within each file	
rmp	boolean; TRUE if peaks are to be removed that do not meet the threshold criteria. Otherwise they will just be flagged.	
snmeth	character; Method to calculate signal to noise ration (either median or mean)	
allfrag boolean; Whether to filter on all fragmentation spectra or or just the fragm tion spectra grouped to XCMS feature		

# Value

Returns a purityA object with the pa@grped\_msms spectra matrices are updated with the following columns

- snr: Signal to noise ratio (calculated at scan level)
- ra: Relative abundance (calculated at scan level)
- purity\_pass\_flag: Precursor ion purity flag (1 pass, 0 fail)
- intensity\_pass\_flag: Intensity flag (1 pass, 0 fail)
- snr\_pass\_flag: Signal-to-noise pass flag (1 pass, 0 fail)
- ra\_pass\_flag: Relative abundance pass flag (1 pass, 0 fail)
- pass\_flag: Overall pass flag, all flags must pass for this to pass (1 pass, 0 fail)

#### **Examples**

```
#msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pa
#xset <- xcms::xcmsSet(msmsPths)
#xset <- xcms::group(xset)
#xset <- xcms::retcor(xset)
#xset <- xcms::group(xset)
#pa <- purityA(msmsPths)</pre>
```

filterp,purityD-method

```
#pa <- frag4feature(pa, xset)
pa <- readRDS(system.file("extdata", "tests", "purityA", "2_frag4feature_pa.rds", package="msPurity"))
pa <- filterFragSpectra(pa)</pre>
```

```
filterp,purityD-method
```

Filter out peaks based on intensity and RSD criteria

# **Description**

Uses a purityD object remove peaks from either (or both) samples and blanks that are either below an intensity threshold or greater than a Relative Standard Deviation (RSD) threshold

#### Usage

```
## S4 method for signature 'purityD'
filterp(Object, thr = 5000, rsd = 20,
   sampleOnly = TRUE)
```

# **Arguments**

Object object; purityD object

thr numeric; intensity threshold

rsd numeric; rsd threshold

sampleOnly boolean; if only the sample (not blanks) should be filtered

# Value

purityD object

# **Examples**

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)

ppDIMS <- purityD(inDF, cores=1)
ppDIMS <- averageSpectra(ppDIMS)
ppDIMS <- filterp(ppDIMS, thr = 5000)</pre>
```

flag\_remove

flag_remove	Flag and remove unwanted peaks
-------------	--------------------------------

# **Description**

On an xcmsSet object, filter flag and remove unwanted peaks. When the peaks are removed, the the xcmsSet object can be regrouped using xcms::group. The function then checks if any blank peaks are still present and the process is repeated.

The output is a list of the updated xcmsSet object, grouped peaklist and the blank removed peaks

# Usage

```
flag_remove(xset, pol = NA, rsd_i_blank = NA, minfrac_blank = 0.5,
    rsd_rt_blank = NA, ithres_blank = NA, s2b = 10,
    ref.class = "blank", egauss_thr = NA, rsd_i_sample = NA,
    minfrac_sample = 0.7, rsd_rt_sample = NA, ithres_sample = NA,
    minfrac_xcms = 0.7, mzwid = 0.025, bw = 5, out_dir = ".",
    temp_save = FALSE, remove_spectra = TRUE, grp_rm_ids = NA)
```

# **Arguments**

8	
xset	object; xcmsSet object
pol	str; polarity (just used for naming purpose for files being saved) [positive, negative, $NA$ ]
rsd_i_blank	numeric; RSD threshold for the blank
minfrac_blank	numeric; minimum fraction of files for features needed for the blank
rsd_rt_blank	numeric; RSD threshold for the RT of the blank
ithres_blank	numeric; Intensity threshold for the blank
s2b	numeric; fold change (sample/blank) needed for sample peak to be allowed. e.g. if s2b set to 10 and the recorded sample 'intensity' value was 100 and blank = $10.1000/10 = 100$ so sample has fold change higher than the threshold and the peak is not considered a blank
ref.class	str; A string representing the class that will be used for the blank.
egauss_thr	numeric; Threshold for filtering out non gaussian shaped peaks. Note this only works if the verbose option was set for XCMS;
rsd_i_sample	numeric; RSD threshold for the sample
minfrac_sample	numeric; minimum fraction of files for features needed for the sample
rsd_rt_sample	numeric; RSD threshold for the RT of the sample
ithres_sample	numeric; Intensity threshold for the sample
minfrac_xcms	numeric; minfrac for xcms grouping
mzwid	numeric; xcms grouping parameter
bw	numeric; xcms grouping parameter
out_dir	str; out directory
temp_save	boolean; Assign True if files for each step saved (for testing purpsoses)
remove_spectra	bool; TRUE if flagged spectra is to be removed
grp_rm_ids	vector; vector of grouped_xcms peaks to remove (coresponds to the row from

xcms::group output)

#### Value

list(xset, grp\_peaklist, removed\_peaks)

#### **Examples**

```
msPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE)
xset <- xcms::xcmsSet(msPths)
xset@phenoData[,1] <- c('blank', 'blank', 'sample', 'sample')
xset <- xcms::group(xset)
fr = flag_remove(xset)</pre>
```

frag4feature, purityA-method

Using a purityA object, link MS/MS data to XCMS features

# **Description**

#### General

Assign fragmentation spectra (MS/MS) stored within a purityA class object to grouped features within an XCMS xset object.

XCMS calculates individual chromatographic peaks for each mzML file (saved in xset@peaks), these are then grouped together (using xcms.group). Ideally the mzML files that contain the MS/MS spectra also contain sufficient MS1 scans for XCMS to detect MS1 chromatographic features. If this is the case, to determine if a MS2 spectra is to be linked to an XCMS grouped feature, the associated acquisition time of the MS/MS event has to be within the retention time window defined for the individual peaks associated for each file. The precursor m/z value also has to be within the user ppm tolerance to XCMS feature.

See below for representation of the linking (the \*——\* represent a many-to-many relationship) e.g. 1 or more MS/MS events can be linked to 1 or more individual feature and an individual XCMS feature can be linked to 1 or more grouped XCMS features

• [grouped XCMS feature - across files] \*——\* [individual XCMS feature - per file] \*——\* [MS/MS spectra]

Alternatively, if the "useGroup" argument is set to TRUE, the full width of the grouped peak (determined as the minimum rtmin and maximum rtmax of the all associated individual peaks) will be used. This option should be used if the mzML file with MS/MS has very limited MS1 data and so individual chromatographic peaks might not be detected with the mzML files containing the MS/MS data. However, it should be noted this may lead to potential inaccurate linking.

• [grouped XCMS peaks] \*——\* [MS/MS spectra]

#### Example LC-MS/MS processing workflow

The purityA object can be used for further processing including linking the fragmentation spectra to XCMS features, averaging fragmentation, database creation and spectral matching (from the created database). See below for an example workflow

- Purity assessments
  - (mzML files) -> purityA -> (pa)
- · XCMS processing

- (mzML files) -> xcms.xcmsSet -> xcms.merge -> xcms.group -> xcms.retcor -> xcms.group -> (xset)
- Fragmentation processing
  - (xset, pa) -> frag4feature -> filterFragSpectra -> averageAllFragSpectra -> createDatabase
     -> spectralMatching -> (sqlite spectral database)

#### **Additional notes**

- If using only a single file, then grouping still needs to be performed within XCMS before frag4feature can be used.
- Fragmentation spectra below a certain precursor ion purity can be be removed (see plim argument).
- A SQLite database can be created directly here but the functionality has been deprecated and the createDatabase function should now be used
- Can experience some problems when using XCMS version < 3 and obiwarp retention time correction.

# Usage

```
## S4 method for signature 'purityA'
frag4feature(pa, xset, ppm = 5, plim = NA,
  intense = TRUE, convert2RawRT = TRUE, useGroup = FALSE,
  create_db = FALSE, out_dir = ".", db_name = NA,
  grp_peaklist = NA, use_group = NA)
```

style consistency)

# **Arguments**

Ę	guments	
	ра	object; purityA object
	object; xcmsSet object derived from the same files as those used to creat purityA object	
	ppm	numeric; ppm tolerance between precursor mz and XCMS feature mz
	plim	numeric; minimum purity of precursor to be included
	intense	boolean; If TRUE the most intense precursor will be used. If FALSE the precursor closest to the center of the isolation window will be used
	convert2RawRT	boolean; If retention time correction has been used in XCMS set this to TRUE
	useGroup	boolean; Ignore individual peaks and just find matching fragmentation spectra within the (full) rtmin rtmax of each grouped feature
	create_db	boolean; (Deprecated, to be removed - use createDatabase function) SQLite database will be created of the results
	out_dir	character; (Deprecated, to be removed - use createDatabase function) Path where database will be created
	db_name	character; (Deprecated, to be removed - use createDatabase function) If create_db is TRUE, a custom database name can be used, default is a time stamp
	grp_peaklist	dataframe; (Deprecated, to be removed - use createDatabase function) Can use any peak dataframe to add to databse. Still needs to be derived from the xset object though
	use_group	boolean; (Deprecated, to be removed - replaced with useGroup argument for

Getfiles 25

#### Value

Returns a purityA object (pa) with the following slots populated:

• pa@grped\_df: A dataframe of the grouped XCMS features linked to the associated fragmentation spectra precursor details is recorded here

- pa@grped\_ms2: A list of fragmentation spectra associated with each grouped XCMS feature is recorded here
- pa@f4f\_link\_type: The linking method is recorded here (e.g. individual peaks or grouped "useGroup=TRUE")

#### **Examples**

```
msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pat
xset <- xcms::xcmsSet(msmsPths, nSlaves = 1)
xset <- xcms::group(xset)
xset <- xcms::retcor(xset)
xset <- xcms::group(xset)

pa <- purityA(msmsPths)
pa <- frag4feature(pa, xset)</pre>
```

Getfiles

Get files for DI-MS processing

#### **Description**

Takes in a folder path and outputs the a data frame structure for purityD. Function modified from mzmatch.

# Usage

```
Getfiles(projectFolder = NULL, recursive = FALSE, pattern = ".csv",
  check = TRUE, raw = FALSE, peakout = NA, cStrt = TRUE,
  mzml_out = FALSE)
```

# Arguments

projectFolder character; Directory path

recursive boolean; Recursively check for files pattern character; File suffix to check for boolean; Check with a GUI the files

 $\begin{array}{ll} \text{raw} & (\text{REDUNDANT}) \\ \text{peakout} & (\text{REDUNDANT}) \end{array}$ 

cStrt boolean; Use the first word as the class name for files

mzml\_out (REDUNDANT)

#### Value

dataframe of files

#### **Examples**

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)</pre>
```

getP,purityD-method

Get peaklist for a purityD object

#### **Description**

output peak list for a purityD object

# Usage

```
## S4 method for signature 'purityD'
getP(x)
```

# **Arguments**

Χ

object; purityD object

#### Value

peaks

# **Examples**

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)
ppDIMS <- purityD(fileList=inDF, cores=1, mzML=TRUE)
peaks <- getP(ppDIMS)</pre>
```

```
get_additional_mzml_meta
```

Get additional mzML meta

# Description

Extract the filter strings 'accession MS:1000512' from an mzML file. Called header in thermo software. Enables quick access to various information regarding each scan

# Usage

```
get_additional_mzml_meta(mzml_pth)
```

# **Arguments**

mzml\_pth

character; mzML path

#### Value

dataframe of meta info

# **Examples**

```
mzml_pth <- system.file("extdata", "dims", "mzML", 'B02_Daph_TEST_pos.mzML', package="msPurityData")
meta_df <- get_additional_mzml_meta(mzml_pth)</pre>
```

groupPeaks,purityD-method

Using purityD object, group multiple peaklists by similar mz values (mzML or .csv)

#### **Description**

Uses a purityD object to group all the peaklists in the 'avPeaks\$processing' slot

# Usage

```
## S4 method for signature 'purityD'
groupPeaks(Object, ppm = 3, sampleOnly = FALSE,
   clustType = "hc")
```

# **Arguments**

Object object = purityD object

ppm numeric = The ppm tolerance to group peaklists sampleOnly = if TRUE the sample peaks will only be grouped

clustType = if 'hc' the hierarchical clustering, if 'simple' the mz values will just be grouped

using a simple 1D method

# Value

data.frame of peaklists grouped together by mz

# **Examples**

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)
ppDIMS <- purityD(fileList=inDF, cores=1, mzML=TRUE)
ppDIMS <- averageSpectra(ppDIMS)
grpedP <- groupPeaks(ppDIMS)</pre>
```

grou	nPea	ksFx
gi ou	pı ca	ハンレハ

Group peaklists from a list of dataframes

#### **Description**

Group a list of dataframes by their m/z values

#### Usage

```
groupPeaksEx(peak_list, cores = 1, clustType = "hc", ppm = 2)
```

# **Arguments**

peak\_list list = A list (named) of dataframes consiting of a least the following columns ['peakID', 'mz']

cores = number of cores used for calculation

clustType = if 'hc' the hierarchical clustering, if 'simple' the mz values will just be grouped using a simple 1D method

numeric = The ppm tolerance to group peaklists

# Value

ppm

data.frame of peaklists grouped together by mz

# **Examples**

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)
ppDIMS <- purityD(fileList=inDF, cores=1, mzML=TRUE)
ppDIMS <- averageSpectra(ppDIMS)
grpedP <- groupPeaks(ppDIMS)</pre>
```

initialize, purityD-method

Constructor for S4 class to represent a DI-MS purityD

# **Description**

The class used to predict purity from an DI-MS dataset.

# Usage

```
## S4 method for signature 'purityD'
initialize(.Object, fileList, cores = 1,
    mzML = TRUE, mzRback = "pwiz")
```

iwNormGauss 29

# **Arguments**

.Object	object; purityD object
fileList	data.frame; created using GetFiles, data.frame with filepaths and sample class information
cores	numeric; Number of cores used to perform Hierarchical clustering WARNING: memory intensive, default 1
mzML	boolean; TRUE if mzML to be used FALSE if .csv file to be used
mzRback	character; backend to use for mzR parsing

#### Value

purityD object

# **Examples**

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)
ppDIMS <- purityD(fileList=inDF, cores=1, mzML=TRUE)</pre>
```

iwNormGauss	Gaussian normalisation for isolation window efficiency
-------------	--

# Description

Creates a function based on a gaussian curve shape that will normalise any intensity values within a defined isolation window.

The function that is created will output a value between 0 to 1 based on the position between the minOff and maxOff params. (The value 1.0 being equivalent to 100

# Usage

```
iwNormGauss(sdlim = 3, minOff = -0.5, maxOff = +0.5)
```

# Arguments

sdlim	numerical; Standard deviation limit for gaussian curve	
minOff	numerical; Offset to the 'left' for the precursor range. (Should be negative)	
maxOff	character; Offset to the 'left' for the precursor range. (Should be positive)	

# Value

normalisation function for selected range.

30 iwNormQE.5

#### **Examples**

```
iwNormFun <- iwNormGauss(minOff=-0.5, maxOff=0.5)
pm <- data.frame(mz=c(99.5, 99.9, 100, 100.1, 100.5),i=c(1000, 1000, 1000, 1000, 1000))
mzmax = 100.5
mzmin = 99.5
middle <- mzmax-(mzmax-mzmin)/2
adjustmz = pm$mz-middle

# normalise the intensities
pm$normi = pm$i*iwNormFun(adjustmz)</pre>
```

iwNormQE.5

Q-Exactive +/- 0.5 range, normalisation for isolation window efficiency

#### **Description**

Creates a function based on a previous experimental analysis of a Q-Exactive at +/- 0.5 isolation window efficiency. See http://pubs.acs.org/doi/abs/10.1021/acs.analchem.6b04358

The function that is created will output a value between 0 to 1 based on the position between the minOff and maxOff params

NOTE: The resulting function will work for values greater that 0.5 and less than -0.5.

This is because (on our instrument tested at least) when using a window of +/- 0.5, the isolation is NOT confined to the +/- 0.5 Da window. Resulting in ions from outside the window being isolated. For this reason the function can normalise values outside of the the +/- 1 Da range. Please see above paper figure 3 for more details.

# Usage

```
iwNormQE.5()
```

#### Value

normalisation function for +/- 0.5 range for Q-Exactive

# **Examples**

```
iwNormFun <- iwNormQE.5()
pm <- data.frame(mz=c(99.5, 99.9, 100, 100.1, 100.5),i=c(1000, 1000, 1000, 1000, 1000))
mzmax = 100.5
mzmin = 99.5
middle <- mzmax-(mzmax-mzmin)/2
adjustmz = pm$mz-middle

# normalise the intensities
pm$normi = pm$i*iwNormFun(adjustmz)</pre>
```

iwNormRcosine 31

		_	
1 W	Norr	nRへへ	sine

Raised cosine normalisation for isolation window efficiency

# **Description**

Creates a function based on a rasied cosine curve shape that will normalise any intensity values within a defined isolation window

The function that is created will output a value between 0 to 1 based on the position between the minOff and maxOff params

# Usage

```
iwNormRcosine(minOff = -0.5, maxOff = +0.5)
```

#### **Arguments**

```
minOff numerical; Offset to the 'left' for the precursor range. (Should be negative)
maxOff character; Offset to the 'left' for the precursor range. (Should be positive)
```

#### Value

normalisation function for selected range

# **Examples**

```
iwNormFun <- iwNormRcosine()
pm <- data.frame(mz=c(99.5, 99.9, 100, 100.1, 100.5),i=c(1000, 1000, 1000, 1000, 1000))
mzmax = 100.5
mzmin = 99.5
middle <- mzmax-(mzmax-mzmin)/2
adjustmz = pm$mz-middle

# normalise the intensities
pm$normi = pm$i*iwNormFun(adjustmz)</pre>
```

pcalc

Perform purity calculation on a peak matrix

#### **Description**

This is the main purity calculation that is performed in purityX, purityD and purityA.

- Takes in a matrix of peaks
- · gets isolation window based on mzmin mzmax
- locates the mz target in the peak matrix
- · removes isotopic peaks
- removes any peaks below limit (percentage of target peak intensity)
- normalises
- Calculates purity: Divides the target peak intensity by the total peak intensity for the isolation window

#### Usage

```
pcalc(peaks, mzmin, mzmax, mztarget, ppm = NA, iwNorm = FALSE,
  iwNormFun = NULL, ilim = 0, targetMinMZ = NA, targetMaxMZ = NA,
  isotopes = FALSE, im = NULL)
```

#### **Arguments**

peaks matrix; Matrix of peaks consisting of 2 columns: mz and i

mzmin numeric; Isolation window (min)
mzmax numeric; Isolation window (max)

mztarget numeric; The mz window to target in the isolation window

ppm numeric; PPM tolerance for the target mz value. If NA will presume target-

MinMZ and targetMaxMZ will be used

iwNorm boolean; If TRUE then the intensity of the isolation window will be normalised

based on the iwNormFun function

iwNormFun function; A function to normalise the isolation window intensity. The default

function is very generalised and just accounts for edge effects

ilim numeric; All peaks less than this percentage of the target peak will be removed

from the purity calculation, default is 5% (0.05)

targetMinMZ numeric; Range to look for the mztarget (min)
targetMaxMZ numeric; Range to look for the mztarget (max)
isotopes boolean; TRUE if isotopes are to be removed

im matrix; Isotope matrix, default removes C13 isotopes (single, double and triple

bonds)

#### Value

a vector of the purity score and the number of peaks in the window e.g c(purity, pknm)

#### **Examples**

```
pm <- rbind(c(100, 1000),c(101.003, 10))
pcalc(pm, mzmin = 98, mzmax = 102, mztarget=100, ppm=5)
pcalc(pm, mzmin = 98, mzmax = 102, mztarget=100, ppm=5, isotopes = TRUE)</pre>
```

purityA Assess the acquired precursor ion purity of MS/MS spectra (constructor)

# Description

#### General

Given a vector of LC-MS/MS or DI-MS/MS mzML file paths calculate the precursor ion purity of each MS/MS scan.

The precursor ion purity represents the measure of the contribution of a selected precursor peak in an isolation window used for fragmentation and can be used as away of assessing the spectral quality and level of "contamination" of fragmentation spectra.

The calculation involves dividing the intensity of the selected precursor peak by the total intensity of the isolation window and is performed before and after the MS/MS scan of interest and interpolated at the recorded time of the MS/MS acquisition.

Additionally, isotopic peaks are annotated and omitted from the calculation, low abundance peaks are removed that are thought to have minor contribution to the resulting MS/MS spectra and the isolation efficiency of the mass spectrometer can be used to normalise the intensities used for the calculation.

The output is a purityA S4 class object (referred to as pa for convenience throughout the manual). The object contains a slot (pa@puritydf) where the details of the purity assessments for each MS/MS scan. The purityA object can then be used for further processing including linking the fragmentation spectra to XCMS features, averaging fragmentation, database creation and spectral matching (from the created database).

# Example LC-MS/MS processing workflow

The purityA object can be used for further processing including linking the fragmentation spectra to XCMS features, averaging fragmentation, database creation and spectral matching (from the created database). See below for an example workflow

- Purity assessments
  - (mzML files) -> purityA -> (pa)
- XCMS processing
  - (mzML files) -> xcms.xcmsSet -> xcms.merge -> xcms.group -> xcms.retcor -> xcms.group -> (xset)
- Fragmentation processing
  - (xset, pa) -> frag4feature -> filterFragSpectra -> averageAllFragSpectra -> createDatabase
     -> spectralMatching -> (sqlite spectral database)

# **Isolation efficiency**

When the isolation efficiency of an MS instrument is known the peak intensities within an isolation window can be normalised for the precursor purity calculation. The isolation efficiency can be estimated by measuring a single precursor across a sliding window. See figure 3 from the original msPurity paper (Lawson et al 2017). This has been experimentally measured for a Thermo Fisher Q-Exactive Mass spectrometer using 0.5 Da windows and can be set within msPurity by using msPurity::iwNormQE.5() as the input to the iwNormFunc argument.

Other options to model the isolation efficiency the gaussian isolation window msPurity::iwNormGauss(minOff=-0.5, maxOff = 0.5) or a R-Cosine window msPurity::iwNormRCosine(minOff=-0.5, maxOff=0.5). Where the minOff and maxOff can be altered depending on the isolation window size.

A user can also define their own normalisation function. The only requirement of the function is that given a value between the minOff and maxOff a normalisation value between 0-1 is returned.

# Notes regarding instrument specific isolation window offsets used:

- The isolation widths offsets will be automatically determined from extracting metadata from the mzML file. However, for some vendors though this is not recorded, in these cases the offsets should be given by the user as an argument (offsets).
- In the case of Agilent only the "narrow" isolation is supported. This roughly equates to +/- 0.65 Da (depending on the instrument). If the file is detected as originating from an Agilent instrument the isolation widths will automatically be set as +/- 0.65 Da.

#### Usage

```
purityA(fileList, cores = 1, mostIntense = FALSE, nearest = TRUE,
  offsets = NA, plotP = FALSE, plotdir = NULL, interpol = "linear",
  iwNorm = FALSE, iwNormFun = NULL, ilim = 0.05, mzRback = "pwiz",
  isotopes = TRUE, im = NULL)
```

#### **Arguments**

fileList vector; mzML file paths

cores numeric; Number of cores to use

mostIntense boolean; True if the most intense peak is used for calculation. Set to FALSE if

the peak closest to mz value detailed in mzML meta data.

nearest boolean; True if the peak selected is from either the preceding scan or the near-

est.

offsets vector; Override the isolation offsets found in the mzML file e.g. c(0.5, 0.5)

plotP boolean; If TRUE a plot of the purity is to be saved

plotdir vector; If plotP is TRUE plots will be saved to this directory

interpol character; type of interolation to be performed "linear" or "spline" (Spline option

is only included for testing purposes, linear should be used for all standard cases,

isotope removal is also not available for the spline option)

iwNorm boolean; If TRUE then the intensity of the isolation window will be normalised

based on the iwNormFun function

iwNormFun function; A function to normalise the isolation window intensity. The default

function is very generalised and just accounts for edge effects

ilim numeric; All peaks less than this percentage of the target peak will be removed

from the purity calculation, default is 5% (0.05)

mzRback character; backend to use for mzR parsing isotopes boolean; TRUE if isotopes are to be removed

im matrix; Isotope matrix, default removes C13 isotopes (single, double and triple

onds)

#### Value

Returns a purityA object (pa) with the pa@puritydf slot updated

The purity dataframe (pa@puritydf) consists of the following columns:

- pid: unique id for MS/MS scan
- fileid: unique id for mzML file
- seqNum: scan number
- precursorIntensity: precursor intensity value as defined in the mzML file
- precursorMZ: precursor m/z value as defined in the mzML file
- precursorRT: precursor RT value as defined in the mzML file
- precursorScanNum: precursor scan number value as defined in mzML file
- id: unique id (redundant)
- filename: mzML filename
- precursorNearest: MS1 scan nearest to the MS/MS scan

• aMz: The m/z value in the "precursorNearest" MS1 scan which most closely matches the precursorMZ value provided from the mzML file

- aPurity: The purity score for aMz
- apkNm: The number of peaks in the isolation window for aMz
- iMz: The m/z value in the precursorNearest MS1 scan that is the most intense within the isolation window.
- iPurity: The purity score for iMz
- ipkNm: The number of peaks in the isolation window for iMz
- inPurity: The interpolated purity score (the purity score is calculated at neighbouring MS1 scans and interpolated at the point of the MS/MS acquisition)
- inpkNm: The interpolated number of peaks in the isolation window

The remaining slots for purity A class include

- pa@cores: The number of CPUs to be used for any further processing with this purity A object
- pa@fileList: list of the mzML files that have been processed
- pa@mzRback: The backend library used by mzR to extract information from the mzML file (e.g. pwiz)
- pa@grped\_df: If frag4feature has been performed, a dataframe of the grouped XCMS features linked to the associated fragmentation spectra precursor details is recorded here
- pa@grped\_ms2: If frag4feature has been performed, a list of fragmentation spectra associated with each grouped XCMS feature is recorded here
- pa@f4f\_link\_type: If frag4feature has been performed, the 'linking method' is recorded here,
  e.g. 'group' or 'individual'. Default is 'individual', see frag4feature documentation for more
  details
- pa@av\_spectra: if averageIntraFragSpectra, averageInterFragSpectra, or averageAllFragSpectra have been performed, the average spectra is recorded here
- pa@av\_intra\_params: If averageIntraFragSpectra has been performed, the parameters are recorded here
- pa@av\_inter\_params: if averageInterFragSpectra has been performed, the parameters are recorded here]
- pa@av\_all\_params: If averageAllFragSpectra has been performed, the parameters are recorded here
- pa@db\_path: If create\_database has been performed, the resulting path to the database is recorded here

36 purityX

purityb-class An 54 class to represent a DI-MS purityb	purityD-class	An S4 class to represent a DI-MS purityD
--	---------------	--

# Description

The class used to assess anticipated purity from a DI-MS run

# **Arguments**

.Object	object; purityD object
fileList	data.frame; Created using GetFiles, data.frame with filepaths and sample class information
cores	numeric; Number of cores used to perform Hierarchical clustering WARNING: memory intensive, default 1
mzML	boolean; TRUE if mzML to be used FALSE if .csv file to be used

# Value

```
purityD object
```

# Examples

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)
ppDIMS <- purityD(fileList=inDF, cores=1, mzML=TRUE)</pre>
```

purityX

Assessing anticipated purity of XCMS features from an LC-MS run

# **Description**

Constructor for the purityX class.

Given an XCMS object get the anticipated precursor purity of the grouped peaks

# Usage

```
purityX(xset, purityType = "purityFWHMmedian", offsets = c(0.5, 0.5),
  fileignore = NULL, cores = 1, xgroups = NULL, iwNorm = FALSE,
  iwNormFun = NULL, ilim = 0.05, plotP = FALSE, mzRback = "pwiz",
  isotopes = FALSE, im = NULL, singleFile = 0,
  rtrawColumns = FALSE, saveEIC = FALSE, sqlitePth = NULL)
```

purityX 37

## Arguments

xset		object; xcms object
purityTy	pe	character; Area and average used for the purity predictions. Options are "purityFWHMmedian", "purityFWmedian", "purityFWHMmean"
offsets		vector; vector of the isolation window upper and lower offsets
fileigno	re	vector; vector of files to ignore for the prediction calculation
cores		numeric; number of cores to use
xgroups		vector; vector of xcms groups to perform prediction on
iwNorm		boolean; if TRUE then the intensity of the isolation window will be normalised based on the iwNormFun function
iwNormFu	ın	function; A function to normalise the isolation window intensity. The default function is very generalised and just accounts for edge effects
ilim		numeric; All peaks less than this percentage of the target peak will be removed from the purity calculation, default is $5\%~(0.05)$
plotP		boolean; TRUE if plot of the EIC of feature and associated contamination is the be save to the working directory
mzRback		character; backend to use for mzR parsing
isotopes	i	boolean; TRUE if isotopes are to be removed
im		matrix; Isotope matrix, default removes C13 isotopes (single, double and triple bonds)
singleFi	le	numeric; If just a single file for purity is to be calculated (rather than the grouped XCMS peaks). Uses the index of the files in xcmsSet object. If zero this is ignored.
rtrawCol	umns	boolean; TRUE if the rt_raw values are included as additional columns in the @peaks slot (only required if using the obiwarp)
saveEIC		boolean; If True extracted ion chromatograms will be saved to SQLite database
sqlitePt	h	character; If saveEIC True, then a path to sqlite database can be used. If NULL then a database will be created in the working directory called eics

## Value

a purityX object containing a dataframe of predicted purity scores

# **Examples**

```
msPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, patter
xset <- xcms::xcmsSet(msPths)
xset <- xcms::group(xset)
xset <- xcms::retcor(xset)
xset <- xcms::group(xset)
ppLCMS <- purityX(xset, cores = 1, xgroups = c(1, 2))</pre>
```

spectralMatching

Spectral matching for LC-MS/MS datasets

## **Description**

# General

Perform spectral matching to spectral libraries for an LC-MS/MS dataset.

The spectral matching is performed from a **Query** SQLite spectral-database against a **Library** SQLite spectral-database.

The SQLite schema of the spectral database can be detailed Schema details can be found here.

The query spectral-database in most cases should contain be the "unknown" spectra database generated the msPurity function createDatabase as part of a msPurity-XCMS data processing workflow.

The library spectral-database in most cases should contain the "known" spectra from either public or user generated resources. The library SQLite database by default contains data from MoNA including Massbank, HMDB, LipidBlast and GNPS. A larger database can be downloaded from here. To create a user generated library SQLite database the following tool can be used to generate a SQLite database from a collection of MSP files: msp2db. It should be noted though, that as long as the schema of the spectral-database is as described here, then any database can be used for either the library or query - even allowing for the same database to be used.

The spectral matching functionality has four main components, spectral filtering, spectral alignment, spectral matching, and summarising the results.

Spectral filtering is simply filtering both the library and query spectra to be search against (e.g. choosing the library source, instrument, retention time, precursor PPM tolerance etc).

The spectral alignment stage involves aligning the query peaks to the library peaks. The approach used is similar to modified pMatch algorithm described in Zhou et al 2015.

The spectral matching of the aligned spectra is performed against a combined intensity and m/z weighted vector - created for both the query and library spectra (wq and wl). See below:

40 spectralMatching

$$w = intensity^x * mz^y$$

Where x and y represent weight factors, defaults to x=0.5 and y=2 as per MassBank. These can be adjusted by the user though.

The aligned weighted vectors are then matched using dot product cosine, reverse dot product cosine and the composite dot product. See below for dot product cosine equation.

$$dpc = wq * wl/\sqrt{\sum wq^2} * \sqrt{\sum wl^2}$$

See the vigenttes for more details regarding matching algorithms used.

#### Example LC-MS/MS processing workflow

- · Purity assessments
  - (mzML files) -> purityA -> (pa)
- · XCMS processing
  - (mzML files) -> xcms.xcmsSet -> xcms.merge -> xcms.group -> xcms.retcor -> xcms.group -> (xset)
- Fragmentation processing
  - (xset, pa) -> frag4feature -> filterFragSpectra -> averageAllFragSpectra -> createDatabase
     -> spectralMatching -> (sqlite spectral database)

#### Usage

```
spectralMatching(q_dbPth, l_dbPth = NA, q_purity = NA,
   q_ppmProd = 10, q_ppmPrec = 5, q_raThres = NA, q_pol = NA,
   q_instrumentTypes = NA, q_instruments = NA, q_sources = NA,
   q_spectraTypes = "av_all", q_pids = NA, q_rtrange = c(NA, NA),
   q_spectraFilter = TRUE, q_xcmsGroups = NA, q_accessions = NA,
   l_purity = NA, l_ppmProd = 10, l_ppmPrec = 5, l_raThres = NA,
   l_pol = "positive", l_instrumentTypes = NA, l_instruments = NA,
   l_sources = NA, l_spectraTypes = NA, l_pids = NA,
   l_rtrange = c(NA, NA), l_spectraFilter = FALSE, l_xcmsGroups = NA,
   l_accessions = NA, usePrecursors = TRUE, raW = 0.5, mzW = 2,
   rttol = NA, cores = 1, updateDb = FALSE, copyDb = FALSE,
   outPth = "sm_result.sqlite")
```

#### **Arguments**

q_dbPth	character; Path of the database of queries that will be searched against the library spectra. Generated from createDatabase
l_dbPth	character; path to library spectral SQLite database. Defaults to msPurityData package data.
q_purity	character; Precursor ion purity threshold for the query spectra
q_ppmProd	numeric; ppm tolerance for query product
q_ppmPrec	numeric; ppm tolerance for query precursor
q_raThres	numeric; Relative abundance threshold for query spectra
q_pol	character; Polarity of query spectra ('positive', 'negative', NA).

spectralMatching 41

 $q\_instrumentTypes$ 

vector; Instrument types for query spectra.

q\_instruments vector; Instruments for query spectra (note that this is used in combination

with q\_instrumentTypes - any spectra matching either q\_instrumentTypes or

q\_instruments will be used).

q\_sources vector; Sources of query spectra (e.g. massbank, hmdb).

q\_spectraTypes character; Spectra types of query spectra to perfrom spectral matching e.g. ('scans',

'av\_all', 'intra', 'inter')

q\_pids vector; pids for query spectra (correspond to column 'pid; in s\_peak\_meta)

q\_rtrange vector; retention time range (in secs) of query spectra, first value mininum time

and second value max e.g. c(0, 10) is between 0 and 10 seconds

q\_spectraFilter

boolean; For query spectra, if prior filtering performed with msPurity, flag peaks

will be removed from spectral matching

q\_xcmsGroups vector; XCMS group ids for query spectra q\_accessions vector; accession ids to filter query spectra

1\_purity character; Precursor ion purity threshold for the library spectra (uses interpo-

lated purity - inPurity)

1\_ppmProd numeric; ppm tolerance for library product
1\_ppmPrec numeric; ppm tolerance for library precursor

1\_raThres numeric; Relative abundance threshold for library spectra

1\_pol character; Polarity of library spectra ('positive', 'negative', NA)

 $l\_instrumentTypes$ 

vector; Instrument types for library spectra.

 $l\_instruments$  vector; Instruments for library spectra (note that this is used in combination

with q\_instrumentTypes - any spectra matching either q\_instrumentTypes or

q\_instruments will be used).

1\_sources vector; Sources of library spectra (e.g. massbank, hmdb).

1\_spectraTypes vector; Spectra type of library spectra to perfrom spectral matching with e.g.

('scans', 'av\_all', 'intra', 'inter')

1\_pids vector; pids for library spectra (correspond to column 'pid; in s\_peak\_meta)

1\_rtrange vector; retention time range (in secs) of library spectra, first value mininum time

and second value max e.g. c(0, 10) is between 0 and 10 seconds

l\_spectraFilter

boolean; For library spectra, if prior filtering performed with msPurity, flag

peaks will be removed from spectral matching

1\_xcmsGroups vector; XCMS group ids for library spectra 1\_accessions vector; accession ids to filter library spectra

usePrecursors boolean; If TRUE spectra will be filtered by similarity of precursors based on

ppm range defined by l\_ppmPrec and q\_ppmPrec

raW numeric; Relative abundance weight for spectra (default to 0.5 as determined by

massbank for ESI data)

mzW numeric; mz weight for spectra (default to 2 as determined by massbank for ESI

data)

42 spectralMatching

rttol numeric; Tolerance in time range between the library and query spectra reten-

tion time

cores numeric; Number of cores to use

updateDb boolean; Update the Query SQLite database with the results

copyDb boolean; If updating the database - perform on a copy rather that the original

query database

outPth character; If copying the database - the path of the new database file

#### Value

Returns a list containing the following elements

#### q\_dbPth

Path of the query database (this will have been updated with the annotation results if updateDb argument used)

#### matchedResults

All matched results from the query spectra to the library spectra. Contains the following columns

- dpc dot product cosine of the match
- rdpc reverse dot product cosine of the match
- cdpc composite dot product cosine of the match
- mcount number of matching peaks
- · allcount total number of peaks across both query and library spectra
- mpercent percentage of matching peaks across both query and library spectra
- · accession accession of library match
- name name of library match
- inchikey inchikey of library match
- · lpid pid in database of library match
- qpid pid in database of query match
- mid id of the match

## xcmsMatchedResults

If the query spectra had XCMS based chromotographic peaks tables (e.g c\_peak\_groups, c\_peaks) in the sqlite database - it will be possible to summarise the matches for each XCMS grouped feature. The dataframe contains the following columns

- pid pid in database of query match
- grpid grpid of the XCMS grouped feature for query match
- mz derived from XCMS grouped feature
- mzmin derived from XCMS grouped feature
- · mzmax derived from XCMS grouped feature
- rt derived from XCMS grouped feature
- rtmin derived from XCMS grouped feature
- · rtmax derived from XCMS grouped feature
- · npeaks derived from XCMS grouped feature
- grp\_name derived from XCMS grouped feature

spectral\_matching 43

- dpc dot product cosine of the match
- rdpc reverse dot product cosine of the match
- cdpc composite dot product cosine of the match
- mcount number of matching peaks
- · allcount total number of peaks across both query and library spectra
- mpercent percentage of matching peaks across both query and library spectra
- · accession accession of library match
- name name of library match
- · inchikey inchikey of library match
- lpid pid in database of library match
- mid id of the match

list of database details and dataframe summarising the results for the xcms features

#### **Examples**

```
#msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pa
#xset <- xcms::xcmsSet(msmsPths)
#xset <- xcms::group(xset)

#xset <- xcms::group(xset)

#xset <- xcms::group(xset)

#pa <- purityA(msmsPths)
#pa <- frag4feature(pa, xset)
#pa <- filterFragSpectra(pa, allfrag=TRUE)
#pa <- averageAllFragSpectra(pa)
#q_dbPth <- createDatabase(pa, xset)
q_dbPth <- system.file("extdata", "tests", "db", "createDatabase_example.sqlite", package="msPurity")
result <- spectralMatching(q_dbPth, q_xcmsGroups = c(12, 27), cores=1, l_accessions=c('CCMSLIB00000577898','C)</pre>
```

spectral\_matching

Spectral matching [deprecated]

## Description

Perform spectral matching to spectral libraries using dot product cosine on a LC-MS/MS dataset and link to XCMS features.

msPurity::spectral\_matching is deprecated - please use msPurity::spectralMatching for future use

## Usage

```
spectral_matching(query_db_pth, ra_thres_1 = 0, ra_thres_q = 2,
  cores = 1, pol = "positive", ppm_tol_prod = 10, ppm_tol_prec = 5,
  score_thres = 0.6, topn = NA, db_name = NA, library_db_pth = NA,
  instrument_types = NA, library_sources = "massbank", scan_ids = NA,
  pa = NA, xset = NA, grp_peaklist = NA, out_dir = ".",
  ra_w = 0.5, mz_w = 2, spectra_type_q = "scans", ra_thres_t = NA,
  target_db_pth = NA, rt_range = c(NA, NA), rttol = NA,
  match_alg = "dpc")
```

44 spectral\_matching

#### **Arguments**

query\_db\_pth character; Path of the database of targets (queries) that will be searched against

the library spectra. Generated either from frag4feature or from create\_database

functions.

ra\_thres\_1 numeric; Relative abundance threshold for library spectra

ra\_thres\_q numeric; Relative abundance threshold for target (query) spectra (Peaks below

this RA threshold will be excluded)

cores numeric; Number of cores to use

pol character; Polarity ['positive' or 'negative']

ppm\_tol\_prod numeric; PPM tolerance to match to product

ppm\_tol\_prec numeric; PPM tolerance to match to precursor

score\_thres numeric; Dot product cosine score threshold

numeric [optional]; Only use top n matches

db\_name character [optional]; Name of the result database (e.g. can use CAMERA peak-

list)

library\_db\_pth character [optional]; path to library spectral SQLite database. Defaults to msPu-

rityData package data.

instrument\_types

vector [optional]; Vector of instrument types, defaults to all

library\_sources

vector [optional]; Vector of library sources. Default option is for massbank only

but the 'lipidblast' library is also available

scan\_ids vector [optional]; Vector of unique scan ids calculated from msPurity "pid".

These scans will on used for the spectral matching. All scans will be used if set

to NA

pa purityA object [optional]; If target\_db\_pth set to NA, a new database can be

created using pa, xset and grp\_peaklist

xset xcms object [optional]; If target\_db\_pth set to NA, a new database can be created

using pa, xset and grp\_peaklist

grp\_peaklist dataframe [optional]; If target\_db\_pth set to NA, a new database can be created

using pa, xset and grp\_peaklist

out\_dir character [optional]; If target\_db\_pth set to NA, Out directory for the SQLite

result database

ra\_w numeric; Relative abundance weight for spectra

mz\_w numeric; mz weight for spectra

spectra\_type\_q character; Type of fragmentation spectra from query to match with "scans" =

all individual scans, "av\_intra" = averaged spectra (intra), "av\_inter" = averaged spectra (inter), "av\_all" = averaged all spectra ignoring inter-intra relationships

ra\_thres\_t numeric [deprecated]; The relative abundance threshold for the query spectra

(use ra\_thres\_q for future use)

target\_db\_pth character [deprecated]; The query database path (use query\_db\_pth for future

use)

rt\_range vector [optional]; Vector of rention time range to filter the library spectra (rtmin,

rtmax). Default is to ignore retention time range

rttol numeric [optional]; Tolerance in time range between the Library and Query

database retention time (in seconds) NA to ignore

match\_alg character; Can either use dot product cosine (dpc) or match factor (mf) for spec-

tral matching. Defaults to dpc

#### Value

list of database details and dataframe summarising the results for the xcms features

#### **Examples**

```
#msmsPths <- list.files(system.file("extdata", "lcms", "mzML", package="msPurityData"), full.names = TRUE, pa
#xset <- xcms::xcmsSet(msmsPths)
#xset <- xcms::group(xset)

#xset <- xcms::group(xset)

#pa <- purityA(msmsPths)
#pa <- frag4feature(pa, xset)
#pa <- averageAllFragSpectra(pa)
#db_pth <- create_database(pa, xset)
#q_dbPth <- system.file("extdata", "tests", "db", "create_database_example.sqlite", package="msPurity")
#result <- spectral_matching(q_dbPth, spectra_type_q="av_all")</pre>
```

subtract, purityD-method

Using Subtract MZ values based on ppm tolerance and noise ratio

## Description

Uses a purityD object with references to multiple MS files. Subtract blank peaks from the sample peaks see subtractMZ for more information

## Usage

```
## S4 method for signature 'purityD'
subtract(Object, byClass = TRUE,
   mapping = c("sample", "blank"), ppm = 5, s2bthres = 10)
```

# **Arguments**

Object object; purityD object

byClass boolean; subtract within each class mapping parameter not functional (TODO)

ppm numeric = ppm tolerance

s2bthres numeric = threshold for the samp2blank (i1/i2)

## Value

purityD object with averaged spectra

## See Also

subtractMZ

46 subtractMZ

#### **Examples**

```
datapth <- system.file("extdata", "dims", "mzML", package="msPurityData")
inDF <- Getfiles(datapth, pattern=".mzML", check = FALSE, cStrt = FALSE)

ppDIMS <- purityD(inDF, cores=1)
ppDIMS <- averageSpectra(ppDIMS)
ppDIMS <- filterp(ppDIMS, thr = 5000)
ppDIMS <- subtract(ppDIMS)</pre>
```

subtractMZ

Subtract MZ values based on ppm tolerance and noise ratio

## **Description**

This function is intended for blank subtraction of mz values from two peaklists. It takes in 2 vectors of mz values and 2 coresponding vectors of Intensity values.

The second mz values are subtracted from the first set within an MZ tolerance.

However, if the mz match but the intensity is above a defined threshold then they are not subtracted

#### Usage

```
subtractMZ(mz1, mz2, i1, i2, ppm = 5, s2bthres = 10)
```

## **Arguments**

```
mz1 vector = mz values to start with

mz2 vector = mz values to subtract

i1 vector = i values for mz1

i2 vector = i values for mz2

ppm numeric = ppm tolerance

s2bthres numeric = threshold for the samp2blank (i1/i2)
```

## Value

a vector of the remaining mz values

## **Examples**

```
mz1 <- c(100.001, 200.002, 300.302)
mz2 <- c(100.004, 200.003, 500.101)
i1 <- c(100, 100, 100)
i2 <- c(100, 10000, 100)
subtractMZ(mz1, mz2, i1, i2, ppm=5, s2bthres =10)
```

```
validate, purityA-method
```

Validate precursor purity predictions using LC-MS and LC-MS/MS dataset

## **Description**

The method is used to validate the precursor purity predictions made from an LC-MS dataset

#### Usage

```
## S4 method for signature 'purityA'
validate(pa, ppLCMS)
```

## Arguments

pa object; purityA object ppLCMS object; purityX object

#### Value

purityA object

```
writeOut,purityD-method
```

Using purityD object, save peaks as text files

## Description

Uses a purityD object with references to multiple MS files. Predicts the purity of the processed sample files

## Usage

```
## S4 method for signature 'purityD'
writeOut(Object, outDir, original)
```

## Arguments

Object object; purityD object

outDir character; Directory to save text files

original boolean; If the original (unprocessed) files are to be saved to text files

#### Value

purityD object
